Abstract—We propose cognitive spectrum sharing with generalized selection combining (GSC) at the secondary user (SU) in the presence of multiple primary transceivers with outdated channel information. Our main motivation is to determine the impact of GSC and outdated channel information on the outage probability of cognitive spectrum sharing subject to two practical power constraints: 1) maximum transmit power at the SU transmitter, and 2) peak interference temperature at the PU receiver. We derive new closed-form expressions for the exact and asymptotic outage probability in Rayleigh fading. Our expressions provide concise representations of the diversity order and the array gain. We confirm that the diversity order of GSC is entirely dependent on the secondary network and is equal to the available number of receive antennas at the SU. This result is consistent with those of maximal-ratio combining (MRC) and selection combining (SC) in cognitive spectrum sharing. More importantly, our results show that the outage probability decreases with increasing the correlation coefficient of the outdated channel.

Index Terms—Spectrum sharing, diversity combining, generalized selection combining, outdated channel information.

I. INTRODUCTION

Cognitive radio has been proposed as a promising means to cope with the rapid growth of volume-intensive bandwidth-hungry mobile applications such as online gaming, social networking, and high-definition (HD) video streaming. The so-called underlay cognitive radio allows the secondary user (SU) and the primary user (PU) to transmit concurrently in the same spectrum provided that the interference from the SU to the PU does not exceed a predetermined interference threshold [1, 2]. The challenge is to effectively coordinate the transmit power at the SU transmitter (SU-Tx), the interference power at the PU receiver (PU-Rx) from the SU-Tx, and the interference power at the SU receiver (SU-Rx) from the PU transmitter (PU-Tx). While cognitive radio increases the reliability of the secondary network, interference requirements in the primary network are often contradictory [3]. The goal of this paper is therefore to address this delicate balance by proposing generalized selection combining (GSC) at the SU-Rx.

To maximize the link reliability of the secondary network and minimize the interference at the primary network, receive diversity at the SU has been applied in interference-limited spectrum sharing networks. While the outage probability and the bit error rate of cognitive networks with a single antenna at the SUs and the PUs were derived in [4, 5], the capacity of the more general case of multiple antennas at the SU was considered in [6, 7]. In [6, 8], maximal-ratio combining (MRC) was applied at the SU. It was shown in [8] that the capacity of cognitive radio with average interference power constraint increases with MRC. In [6], the impact of peak interference power constraint on the capacity was characterized. Considering GSC at the SU, [7] evaluated the capacity with peak interference power constraint. Apart from capacity, the outage probability is another important metric to comprehend the fundamental limits of cognitive radio [9, 10]. The practical consideration of interference from PU-Tx to SU-Rx was recently examined in [11]. However, references [4–11] have all assumed that the SU has full channel-state information (CSI) between the SU-Tx and PU-Rxs, and the impact of GSC in the presence of multiple primary transceivers is less well understood.

In this paper, we view cognitive radio from the viewpoint of GSC as a low power design in interference-limited spectrum sharing networks under outdated CSI between the SU-Tx and PU-Rxs. We consider a general scenario where the SU transmits in the presence of $M$ PU-Txs and $M$ PU-Rxs. The main objective is to enhance the transmission reliability of the secondary network while strictly meet the interference constraint at the primary network, which can be achieved by varying the number of combined antennas at the SU-Rx using GSC. Compared to other diversity combining techniques, GSC is also capable to combat channel estimation errors by eliminating weaker SIRs [12]. To answer some of the pressing questions that face spectrum sharing networks, we relate the maximum transmit power at the SU-Tx with the peak interference power at the PU-Rxs and the interference power from the PU-Txs. Different from previous studies, with GSC, the SU-Rx is allowed to select a subset of its receive antennas so as to balance the transmit power at SU-Tx and the interference power at PU-Rx in the presence of multiple PU transceivers. By doing so, less transmit power at the SU-Tx is required to achieve the same outage performance, which in turn reduces the interference at the PU-Rxs. Additionally, a flexible back-off power control mechanism is adopted to guarantee the quality of service (QoS) of the primary network.
Owing to this fact, our outcomes are presented in the form of new expressions for the exact and the asymptotic outage probability. Our results bridge the gap between MRC and selection combining (SC) by allowing the SU-Rx to combine the $L_c$ strongest out of its $L$ available receive antennas. We show that the full diversity order is achieved. The diversity order is entirely determined by the secondary network and is equal to $L$. We also present the performance gap between GSC, MRC, and SC as a simple ratio of their respective array gains. An interesting conclusion is reached that $M$ imposes a negative impact on the outage probability, while $L_c$ has a positive impact on the outage probability. Furthermore, the outage probability decreases with increasing correlation coefficient of the outdated CSI channel.

II. NETWORK AND CHANNEL DESCRIPTION

We consider a realistic underlay spectrum sharing network with one pair of SU-transceiver and $M$ pairs of PU-transceivers. In the secondary network, we assume a receiver diversity where the SU-Rx is equipped with $L$ receive antennas. The $L_c$ receive antennas are selected based on the channel from the SU-Tx to the SU-Rx. All other terminals are equipped with only one antenna. We assume that only partial channel knowledge of the interference channel from the SU-Tx to the PU-Rxs is available at the SU-Tx. The CSI of $h_{1m}$ provided to the SU-Tx is outdated due to the time-varying nature of the wireless link [13]. We describe the outdated CSI of the SU-Tx to the $m$th PU-Rx channel using the correlation model [14, 15] as

$$h_{1m} = \rho \hat{h}_{1m} + \sqrt{1 - \rho^2} \varepsilon,$$  \hspace{1cm} (1)

where $m \in \{1, ..., M\}$, $\hat{h}_{1m}$ is the outdated channel information available at the SU-Tx, $\varepsilon$ is a complex Gaussian random variable with zero mean and unit variance, and uncorrelated with $h_{1m}$. The correlation coefficient $\rho$ is a constant, which is used to evaluate the impact of channel estimation error, mobility, and feedback delay on the CSI [15]. Note that we assume that both the outdated channel information $h_{1m}$ and the correlation coefficient $\rho$ are available at SU-Tx.

We assume that both the secondary channel and the primary channel are subject to quasi-static fading where the channel coefficients are constant for each transmission block but vary independently between different blocks. The primary and secondary networks are subject to independent and identically distributed (i.i.d.) Rayleigh fading. The estimated channel power gain from the SU-Tx to the $m$th PU-Rx channel is an exponentially distributed RV with parameter $\frac{1}{\alpha_1}$. The instantaneous channel power gains from the SU-Tx to the $m$th PU-Rx channel, from the $m$th PU-Tx to the $l$th receive antenna at SU-Rx, and from the SU-Tx to the $l$th receive antenna at SU-Rx are exponentially distributed RVs with parameters $\frac{1}{\alpha_2}$ and $\frac{1}{\alpha_3}$, respectively, where $l \in \{1, ..., L\}$ and $\alpha_1 = \rho^2 \alpha_3 + (1 - \rho^2)$. Note that here we mainly focus on the outdated channel effect and the impact of GSC, thus, the different path-loss and shadowing effect between the SU-Tx and PU-Rxs links resulting from the geometry are not taken into consideration in this work. This assumption is also applicable to the scenario where PU-Rxs are located in a compact and small area.

A. Interference Outage Probability

According to underlay spectrum sharing, the interference from the secondary network impinging on the primary network should remain below a pre-defined peak interference temperature $Q$ [16]. When only the outdated interference channel information is available at SU-Tx, this strict interference requirement can not be satisfied at all times. Therefore, the PU-Rxs should tolerate outages occurring for a certain percentage of time, which is named as the interference outage. In [15], it was been proved that the interference outage probability is always 0.5 as long as the maximum transmission power is ignored. Therefore, instead of the strict peak interference constraint, a more flexible constraint known as the power margin, which is based on the interference outage probability is considered to prevent the primary transmission from degradation. The transmit power and the interference outage probability are denoted as

$$P\left(\rho, |\hat{h}_{1m}|^2\right) = \min\left(P_T, k_l \frac{Q}{|\hat{h}_{1m}|^2}\right),$$  \hspace{1cm} (2)

and

$$P_o = 1 - \Pr\left\{\min\left(P_T, k_l \frac{Q}{|\hat{h}_{1m}|^2}\right) |\hat{h}_{1m}|^2 \leq Q\right\},$$  \hspace{1cm} (3)

respectively, where $P_T$ is the maximum available transmit power at the SU-Tx, and $|\hat{h}_{1m}|^2$ is the largest estimated channel power gain from the SU-Tx to the $M$ PU-Rxs available at SU-Tx. We assume the power margin factor $k_l$ is 1 for the perfect CSI between SU-Tx and PU-Rx link. Since the closed-form expression for the power margin factor $k_l$ is intractable [14], therein, we numerically evaluate $k_l$ based on (3).

III. SIGNAL-TO-INTERFERENCE RATIO

In the secondary network, GSC is applied to combine the $L_c (1 \leq L_c \leq L)$ antennas with the strongest received signals from $L$ available receive antennas at the SU-Tx. The channel coefficients from the SU-Tx to the $l$th receive antenna at the SU-Rx are denoted as $g_l$ (1 $\leq l \leq L$). Let $|g_1|^2 \geq |g_2|^2 \geq \cdots |g_L|^2 \geq 0$ be the order statistics obtained by sorting $\{g_l\}_{l=1}^L$ in decreasing order of magnitude [7]. After performing GSC [17], the received signal at the SU-Rx is given by

$$y = \frac{G^H}{|G|} G x_T + \sum_{m=1}^{M} \frac{G^H}{|G|} H_{2m} x_m + \frac{G^H}{|G|} n$$  \hspace{1cm} (4)

where $x_T$ is the transmit signal at the SU-Tx, $G = [g_1, g_2, \ldots, g_L]^T$ is the selected channel vector at the SU-Rx, $x_m$ is the transmit signal at the $m$th PU-Tx, $H_{2m}$ is the $L_c \times 1$ channel vector from the $m$th PU-Tx to $L_c$ antennas with strongest receive signals at the SU-Rx, and $n \sim CN(0, \sigma^2 I_{L_c})$ is the $L_c \times 1$ additive white Gaussian noise (AWGN) vector. Similar to some practical applications such as cellular CDMA networks and dense ad hoc networks.
[18], we consider the interference-limited scenario of cognitive networks with multiple primary transceivers where the noise is typically negligible compared to the sum of interferences from the multiple PU-Txs. As such, the SIR can be used interchangeably with SINR without much appreciable loss of accuracy [19–21]. Based on (4), the instantaneous received signal-to-interference ratio (SIR) is given by

$$\hat{\gamma} = \min \left( P_T, \frac{k_l Q}{Y} \right) X,$$

where $X = \|G\|^2$, $Y = \|h_{1m^*}\|^2$, $V = \sum_{m=1}^{M} P_l \left| \frac{G^H H_{m^*}}{\|G\|} \right|^2$ is the interference power from the PU-Txs to the SU-Rx.

**IV. Outage Probability**

**A. Exact Analysis**

Outage probability is an important metric to characterize the performance of cognitive networks in practice. In cognitive networks, an outage occurs if the instantaneous received SIR at the SU drops below a given threshold $\gamma_{th}$. Based on this, the outage probability is formulated as

$$P_{out} = \Pr \{ \hat{\gamma} \leq \gamma_{th} \} = F_{\hat{\gamma}} (\gamma_{th}),$$

where $\Pr \{ \cdot \}$ denotes the probability and $F_{\hat{\gamma}} (\gamma_{th})$ denotes the cumulative distribution function (CDF) of $\hat{\gamma}$. To derive $F_{\hat{\gamma}} (\gamma_{th})$, we first present the statistics of the channel power gain $\|G\|^2$ as follows.

The CDF of $\|G\|^2$ is obtained using [17, eq. (4)] and the multinomial expansion [22] which results in

$$F_{\|G\|^2} (x) = \sum_{S_k \in S_K} \alpha_k x^{\beta_k} e^{-\delta_k x^{\frac{3}{\alpha_3}}},$$

where $S_K = \{ S_k | \sum_{l=0}^{L} m_{k,l} = 1 \}$ with $m_{k,l} \in Z^+$. We note that $S_K$ refers to all possible combinations of $\{m_{k,l}, l = 0, 1, \ldots, L\}$ which satisfy $\sum_{l=0}^{L} m_{k,l} = 1$. The parameters in (7) are defined as

$$\alpha_k = (\varepsilon_0)^{m_{h,0}} \prod_{l=1}^{L} \frac{\varepsilon_l}{\Gamma(l)} m_{h,l} \prod_{l=L_c+1}^{L} \varepsilon_l m_{h,l},$$

$$\beta_k = \sum_{l=1}^{L_c} (l-1)m_{k,l},$$

and

$$\delta_k = \sum_{l=1}^{L_c} m_{k,l} + \sum_{l=L_c+1}^{L} \frac{l}{L_c} m_{k,l},$$

where $\varepsilon_l$ is given by

$$\varepsilon_l = \begin{cases} 1 & l = 0 \\ \alpha_3^{1-l} \left[ -1 + \sum_{k=L_c+1}^{L_c} (-1)^{k-1} \frac{(L_c-k)}{(\varepsilon_l^2-1)^{k-1}} \right] & 1 \leq l < L_c \\ -\alpha_3^{1-L_c} \left[ \frac{(L_c-L_l)}{(\varepsilon_L^2-1)^{L_c-L_l}} \left( \frac{(-1)^L}{(L_c-1)} \right) \right] & L_c < l \leq L_c \end{cases}.$$
B. Asymptotic Analysis

In this subsection, we characterize the asymptotic behavior of the outage probability in the operating region of high $P_T$. Throughout this subsection, we consider that the SU-Tx power is proportional to the PU-Rx interference. This indicates that the diversity order exists when the PU-Rx is able to tolerate a high amount of interference from the SU-Tx. This will benefit the secondary network without violating the transmission at the primary network. With this in mind, we gather a deeper understanding of the effect of power scaling on the outage probability in the operating region of high SIR.

In the high-SIR regime with $P_T \to \infty$, we apply [24, Eq. (3.354.1)] and [24, Eq. (1.211.1)] to derive the first order expansion of $F_{[G]}^2(x)$ as

$$F_{[G]}^2(x) \approx \frac{1}{L_c L_c^{L_c-L_c} e^{L_c^\gamma}} x^{L_c^\gamma}.$$  (17)

Substituting (17) into (25), the asymptotic outage probability with proportional interference power constraint is presented in the following theorem.

**Theorem 2.** When $Q = \mu P_T$, the asymptotic outage probability of spectrum sharing networks with GSC and multiple PU transceivers as $P_T \to \infty$ is derived as

$$P_{out}^\infty \approx (G_c P_T)^{-G_d},$$  (18)

where the diversity order is $G_d = L$ and the array gain is

$$G_c = \left[ \frac{\Theta}{L_c^L} \frac{\Gamma(M+L)}{\Gamma(M)} \right]^{-\frac{1}{2}} \frac{1}{\alpha_2 P_{\gamma_{th}}}.$$  (19)

with $\Theta = (1 - e^{-\frac{k_{th}}{\alpha_2}})^M + \sum_{m=1}^{M} \binom{M}{m} (-1)^{M+1} \frac{L+1}{\alpha_3 (\alpha_2 \alpha_3)}.$

Similarly, the asymptotic outage probability with perfect CSI can be obtained by substituting $k_{th} = 1$ into (18). Based on (18), we confirm that the diversity order is entirely determined by the available number of receive antennas at the SU-Rx $L_c$ but independent of the number of combined antennas at the SU-Rx $L_c$ and the correlation coefficient $\rho$.

We now proceed to examine the outage tradeoff between GSC, MRC, and SC. Given that GSC, MRC, and SC maintain the same diversity order, the tradeoff between them is entirely determined by their respective array gains. Based on our results in (19), we present the following remarks.

**Remark 1:** We set $L_c = L$ in (19) to obtain the array gain of MRC as

$$G_{cMRC} = \left[ \frac{\Theta \Gamma(M+L)}{L \Gamma(M)} \right]^{-\frac{1}{2}} \frac{1}{\alpha_2 P_{\gamma_{th}}}. $$  (20)

Using (19) and (20), the SNR gap between GSC and MRC is expressed as

$$\Delta_1 = 10 \log \left( \frac{G_{cMRC}}{G_{cSC}} \right) = \left( \frac{10}{L_c} \right) \log \left( \frac{L_c^L - L_c^L e_{!}}{L!} \right) \text{ dB}. $$  (21)

**Remark 2:** We set $L_c = 1$ in (19) to obtain the array gain of SC as

$$G_{cSC} = \left[ \frac{\Theta \Gamma(M+L)}{\Gamma(M)} \right]^{-\frac{1}{2}} \frac{1}{\alpha_2 P_{\gamma_{th}}}. $$  (22)

Using (19) and (22), the SIR gap between GSC and SC is expressed as

$$\Delta_2 = 10 \log \left( \frac{G_{cSC}}{G_{cMRC}} \right) = \left( \frac{10}{L_c} \right) \log \left( L_c^L - L_c^L e_{!} \right) \text{ dB}. $$  (23)

**Remark 3:** Using (20) and (22), the SIR gap between MRC and SC is expressed as

$$\Delta_3 = 10 \log \left( \frac{G_{cMRC}}{G_{cSC}} \right) = \left( \frac{10}{L_c} \right) \log (L!) \text{ dB}. $$  (24)

Based on Remarks 1, 2, and 3, we confirm that the SIR gaps $\Delta_1$, $\Delta_2$, and $\Delta_3$ are fully described by two parameters: the number of available receive antennas at the SU-Rx $L_c$ and the number of combined antennas at the SU-Rx $L_c$. 

---

Fig. 1. Outage probability with $L_c = 2$, $L = 3$, $P_0 = 10\%$, and $\rho = 0.9$.

Fig. 2. Outage probability with $M = 6$, $Q = 2P_T$, $P_0 = 10\%$, and $\rho = 0.9$. 

Outage Probability

Numerical examples are provided to highlight the impact of GSC on the performance of underlay spectrum sharing networks with imperfect CSI. In the examples, we assume that the threshold SIR is $\gamma_{th} = 1$ dB and the interference power from PU-Tx is $P_I = 3$ dB. We also set $\hat{\alpha}_1 = 2$, $\alpha_2 = 3$, and $\alpha_3 = 1$. We see a perfect match between the simulations and the exact analytical curves (plotted from (14)). We also see that the asymptotic analytical curves (plotted from (18)) are in precise agreement with the exact analytical curves in the medium-to-high regime of $P_T$.

Fig. 1 plots the outage probability versus $P_T$ as we vary $M$. Here, we set $L = 3$, $L_c = 2$, $P_0 = 10\%$, and $\rho = 0.9$. We observe that the diversity order is independent of $M$ as indicated by the parallel slopes of the asymptotes. The diversity order is entirely determined by the number of antennas at the SU-Rx as $G_d = L$. As expected, the outage probability decreases with decreasing $M$. This is due to the fact that the array gain in (19) increases with decreasing $M$. This result is not surprising, since the interference from the PU-Tx to the SU-Rx increases with increasing $M$, as shown in (5), which negatively impacts the secondary network. We also observe that setting $Q = 2P_T$ achieves a lower outage probability compared to $Q = 0.5P_T$. This is due to the fact that the array gain in (19) increases with increasing $\mu$. In other words, the higher peak interference power constraint at PUs enables more reliable transmission of the secondary network.

Fig. 2 plots the outage probability versus $P_T$ as we vary $L_c$. Here, we set $M = 6$, $Q = 2P_T$, $P_0 = 10\%$, and $\rho = 0.9$. We observe that the diversity order is $G_d = L$ regardless of $L_c$. Setting $L_c = L$ and $L_c = 1$, we obtain the special cases of MRC and SC, respectively. We also observe that the SIR gap between MRC and SC are accurately predicted according to (24). As expected, we observe that the outage probability decreases with increasing $L_c$. This is due to the fact that the array gain increases with increasing $L_c$, as shown in (19). Moreover, we find that the lower outage probability can be achieved by employing more antennas $L$, which can be explained by the fact that the array gain increases with increasing $L$.

Fig. 3 plots the outage probability versus $P_T$ as we vary $\rho$ and $P_0$. Here, we set $M = 5$, $L = 5$, $L_c = 3$, and $Q = 1.5P_T$. We can easily see the same parallel slopes for different coefficients $\rho$, which indicates that the diversity order is independent of $\rho$ and $P_0$. Interestingly, for the case of $P_0 = 0.1$, the outage probability decreases as $\rho$ increases; for the case of $\rho = 0.9$, the outage probability decreases with increasing $P_0$. This can be explained by the fact that increasing $\rho$ and $P_0$ ensure the higher transmit power of the SU-Tx, and thus brings about better outage performance. As expected, for $\rho = 1$, which refers to perfect CSI, the lowest outage probability is achieved.

Fig. 4 plots the outage probability versus $Q$ as we vary $L_c$. Here, we set $M = 5$, $P_T = 25$ dB, $P_0 = 10\%$, and $\rho = 0.9$. As expected, the outage probability decreases with increasing $Q$ when $P_T$ is not a linear function of $Q$. Furthermore, the outage probability decreases with increasing $L_c$.

VI. Conclusions

We proposed generalized selection combining (GSC) in interference-limited spectrum sharing networks with outdated channel state information and multiple PU transceivers. Our aim is to examine the impact of GSC and outdated channel on the outage probability. To facilitate this, we derived new closed-form expressions for the exact and the asymptotic outage probability. The SU-Rx is allowed to combine the $L_c$ strongest antennas out of $L$ antennas. With this in mind, we examined the fundamental question of how $L_c$, $M$, and $\rho$ affect the transmit power at SU-Tx, the interference from SU-Tx to PU-Rx, and the interference from PU-Tx to SU-Rx. The valuable insights are reached that the interference power at the SU-Rx increases as $M$ increases, and the outage probability is improved with more accurate CSI.
APPENDIX A
PROOF OF THEOREM 1

According to (5), the CDF of \( \hat{\gamma} \) conditioned on \( V \) is written as

\[
F_{\hat{\gamma}|V}(\gamma) = \Pr \left\{ \frac{\|G\|^2}{F_T} \cdot |\hat{h}_{1m^*}|^2 < \frac{k_{I_1}}{F_T} \right\}
\]

\[
+ \Pr \left\{ \frac{\|G\|^2}{F_T} \cdot |\hat{h}_{1m^*}|^2 \geq \frac{k_{I_1}}{F_T} \right\} \cdot \frac{I_2(V)}{I_1(V)}
\]

By substituting (7) and (12) into (25), the first term \( I_1(V) \) is obtained as

\[
I_1(V) = \sum_{S_k \in S_K} \alpha_k \left( \frac{\gamma V}{F_T} \right)^{\beta_k} e^{-\frac{k_{I_1} Q}{\alpha_k v_{\gamma} V}} \left( 1 - e^{-\frac{k_{I_1} Q}{\alpha_k v_{\gamma} V}} \right)^M
\]

Integrating (26) with respect to the PDF of \( Z \) given by (13) results in

\[
E_{V} \{ I_1(V) \} = \left( 1 - e^{-\frac{k_{I_1} Q}{\alpha_k v_{\gamma} V}} \right)^M \left( \frac{1}{P_{\alpha_1 \alpha_2}} \right)^M \left( \frac{\alpha_k}{\Gamma(M)} \right)^{\beta_k} \sum_{S_k \in S_K} \alpha_k \frac{\gamma^{\beta_k} e^{-\frac{k_{I_1} Q}{\alpha_k v_{\gamma} V}}}{(\beta_k + M) \Gamma(\beta_k + M)} \left( \frac{\delta_{\alpha_1} \delta_{\alpha_2}^2}{\alpha_3 \delta_{\alpha_3}^2 + \alpha_4 \delta_{\alpha_4}^2} \right)^{\beta_k + M}
\]

Applying the same approach, \( E_{V} \{ I_2(V) \} \) can be derived with the help of [24, Eq. (8.352.2)], [24, Eq. (9.211.4.8)], and the polynomial expansion, which yields

\[
E_{V} \{ I_2(V) \} = \sum_{m=1}^{M} \binom{M}{m} (-1)^{m+1} \sum_{S_k \in S_K} \alpha_k \frac{\gamma^{\beta_k}}{(\beta_k + M) \Gamma(M)} \left( \frac{1}{P_{\alpha_1 \alpha_2}} \right)^M \left( \frac{\delta_{\alpha_1} \delta_{\alpha_2}^2}{\alpha_3 \delta_{\alpha_3}^2 + \alpha_4 \delta_{\alpha_4}^2} \right)^{\beta_k + M} \left( \frac{\gamma}{k_{I_1} Q} \right)^{\beta_k} \Phi_{\beta_k + M, M + i} \left( \frac{1}{P_{\alpha_1 \alpha_2}} e^{\frac{\delta_{\alpha_1} \gamma}{\alpha_3 \delta_{\alpha_3}} + \frac{\delta_{\alpha_2} \gamma}{\alpha_4 \delta_{\alpha_4}}} \right)^{\beta_k + M}
\]

Substituting (27) and (28) into (25), the CDF of the SIR is finally derived as (14).

He has served as Technical Program Committee Member for several IEEE conferences, such as the IEEE International Conference on Communications and the IEEE Global Communications Conference.
Phee Lep Yeoh (S’08, M’12) received the B.E. degree with University Medal from the University of Sydney, Australia, in 2004, and the Ph.D. degree from the University of Sydney, Australia, in 2012. From 2008 to 2012, he was with the Telecommunications Laboratory at the University of Sydney and the Wireless and Networking Technologies Laboratory at the Commonwealth Scientific and Industrial Research Organization (CSIRO), Australia. In 2012, he joined the Department of Electrical and Electronic Engineering at the University of Melbourne, Australia. He is a recipient of the Australian Research Council Discovery Early Career Researcher Award, University of Sydney Postgraduate Award, and CSIRO Postgraduate Scholarship. His research interests include heterogeneous networks, large-scale MIMO, cooperative communications, and cognitive networks.

Ranjan K. Mallik (S’88–M’93–SM’02–F’12) received the B.Tech. degree from the Indian Institute of Technology, Kanpur, in 1987 and the M.S. and Ph.D. degrees from the University of Southern California, Los Angeles, in 1988 and 1992, respectively, all in Electrical Engineering. From August 1992 to November 1994, he was a scientist at the Defence Electronics Research Laboratory, Hyderabad, India, working on missile and EW projects. From November 1994 to January 1996, he was a faculty member of the Department of Electronics and Electrical Communication Engineering, Indian Institute of Technology, Kharagpur. From January 1996 to December 1998, he was with the faculty of the Department of Electronics and Communication Engineering, Indian Institute of Technology, Guwahati. Since December 1998, he has been with the faculty of the Department of Electrical Engineering, Indian Institute of Technology, Delhi, where he is currently a Professor. His research interests are in diversity combining and channel modeling for wireless communications, space-time systems, cooperative communications, multiple-access systems, power line communications, difference equations, and linear algebra.

Dr. Mallik is a member of Eta Kappa Nu. He is also a member of the IEEE Communications, Information Theory, and Vehicular Technology Societies, the American Mathematical Society, and the International Linear Algebra Society, a fellow of IEEE, the Indian National Academy of Engineering, the Indian National Science Academy, The National Academy of Sciences, India, Allahabad, the Indian Academy of Sciences, Bangalore, The World Academy of Sciences - for the advancement of science in developing countries (TWAS), The Institution of Engineering and Technology, U.K., and The Institution of Electronics and Telecommunication Engineers, India, a life member of the Indian Society for Technical Education, and an associate member of The Institution of Engineers (India). He is an Area Editor for the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS. He is a recipient of the Hari Om Ashram Prerit Dr. Vikram Sarabhai Research Award in the field of Electronics, Telematics, Informatics, and Automation, and of the Shanti Swarup Bhatnagar Prize in Engineering Sciences.
