Abstract—We propose cyclic prefix single carrier full-duplex transmission in amplify-and-forward cooperative spectrum sharing networks to achieve multipath diversity and full-duplex spectral efficiency. Integrating full-duplex transmission into cooperative spectrum sharing systems results in two intrinsic problems: 1) the residual loop interference occurs between the transmit and the receive antennas at the secondary relays and 2) the primary users simultaneously suffer interference from the secondary source (SS) and the secondary relays (SRs). Thus, examining the effects of residual loop interference under peak interference power constraint at the primary users and maximum transmit power constraints at the SS and the SRs is a particularly challenging problem in frequency selective fading channels. To do so, we derive and quantitatively compare the lower bounds on the outage probability and the corresponding asymptotic outage probability for max–min relay selection, partial relay selection, and maximum interference relay selection policies in frequency selective fading channels. To facilitate comparison, we provide the corresponding analysis for half-duplex.

Our results show two complementary regions, named as the signal-to-noise ratio (SNR) dominant region and the residual loop interference dominant region, where the multipath diversity and spatial diversity can be achievable only in the SNR dominant region, however the diversity gain collapses to zero in the residual loop interference dominant region.

Index Terms—Cooperative transmission, cyclic prefix single carrier transmission, frequency selective fading, full-duplex transmission, residual loop interference, spectrum sharing.

I. INTRODUCTION

Cognitive radio (CR) has emerged as a revolutionary approach to ease the spectrum utilization inefficiency [2]. In underlay CR networks, the secondary users (SUs) are permitted to access the spectrum of the primary users (PUs), only when the peak interference power constraint at the PUs is satisfied [3]. One drawback of this approach is the constrained transmit power at the SU, which typically results in unstable transmission and restricted coverage [4], [5]. To overcome this challenge, cognitive relaying was proposed as a solution for reliable communication and coverage extension at the secondary network, and interference reduction in the primary network [6]–[12]. In [6] and [7], the generalized selection combining is proposed for spectrum sharing cooperative relay networks. In [8], the performance of cognitive relaying with max-min relay selection was evaluated. In [12], the partial relay selection was proposed in underlay CR networks.

Full-duplex transmission has been initiated as a new technology for the future Wireless Local Area Network (WLAN) [13], WiFi network [14], and the Full-Duplex Radios for Local Access (DUPLO) projects, which aims at developing new technology and system solutions for future generations of mobile data networks [15], 3GPP Long-Term Evolution (LTE), and Worldwide Interoperability for Microwave Access (WiMAX) systems [16]. Recent advances in radio frequency integrated circuit design and complementary metal oxide semiconductor processing have enabled the suppression of residual loop interference. For example, advanced time-domain interference cancellation [17], physical isolation between antennas [18], and antenna directivity [19] have been proposed in existing works. However, these techniques can not enable perfect isolation [20], [21]. Thus, the residual loop interference is still inevitable and significantly deteriorates the performance. Recent research and development on full-duplex relaying (FDR) without utilizing residual loop interference mitigation has attracted increasing attention, considering that FDR offers high spectral efficiency compared to half-duplex relaying (HDR) by transmitting and receiving signals simultaneously using the same channel [22]–[26].

In [25], FDR was first applied in underlay cognitive relay networks with single PU, the optimal power allocation is studied to minimize the outage probability.

The main objective of this paper is to consider the full-duplex spectrum sharing cooperative system with limited transmit power in the transmitter over frequency...
selective fading environment. We can convert the frequency selective fading channels into flat fading channels via Orthogonal Frequency-Division Multiplexing (OFDM) transmission. However, the peak-to-average power ratio (PAPR) is an intrinsic problem in the OFDM-based system. Also, in general, development of the channel equalizer is a big burden to the receiver of single carrier (SC) transmission [27] in the frequency selective fading channels. Thus, to jointly reduce PAPR and channel equalization burden in the practical system, we consider SC with the cyclic prefix (CP). Single carrier (SC) transmission [27] is currently under consideration for IEEE 802.11ad [28] and LTE [29], owing to the fact that SC can provide lower peak-to-average power ratio and power amplifier back-off [30], [31] compared to Orthogonal Frequency-Division Multiplexing (OFDM). In addition, by adding the cyclic prefix (CP) to the front of the transmission symbol block, the multipath diversity gain can be obtained [32].

Different from the aforementioned works, we introduce FDR and amplify and forward (AF) relay selection in SC spectrum sharing systems to obtain spatial diversity and spectral efficiency. The full-duplex relaying proposed in this paper is a promising approach to prevent capacity degradation due to additional use of time slots, even though additional design innovations are needed before it is used in operational networks. We consider three relay selection policies, namely max-min relay selection (MM), partial relay selection (PS), and maximum interference relay selection (MI), each with a different channel state information (CSI) requirement. We consider a realistic scenario where transmissions from the secondary source (SS) and the selected secondary relay (SR) are conducted simultaneously in the presence of multiple PU receivers. Unlike the cognitive half-duplex relay network (CogHRN), in the cognitive full-duplex relay network (CogFRN) the concurrent reception and transmission entails two intrinsic problems: 1) the peak interference power constraint at the PUs are concurrently inflicted on the transmit power at the SS and the SRs; and 2) the residual loop interference due to signal leakage is introduced between the transmit and receive antennas at each SR. Against this background, the preeminent objective of this paper is to characterize the feasibility of full-duplex relaying in the presence of residual loop interference by comparing with half-duplex systems. The impact of frequency selectivity in fading channels is another important dimension far from trivial. For purpose of comparison, we provide the corresponding analysis for cooperative CP-SC CogHRN.

Our main contributions are summarized as follows.

1) Taking into account the residual loop interference, we derive new expressions for the probability density function (PDF) and the cumulative distribution function (CDF) of the signal-to-noise ratio (SNR) of the SS to the kth SR link under frequency selective fading channels.

2) We then derive the expressions for the lower bound on the outage probability. We establish that outage probability floors occur in the residual loop interference dominant region with high SNRs for all the policies in CogFDR. We show that irrespective of the SNR, the MM policy outperforms the PS and the MI policies. We also show that the PS policy outperforms the MI policy.

3) To understand the impact of the system parameters, we derive the asymptotic outage probability and characterize the diversity gain. For FDR, in the residual loop interference dominant region, we see that the asymptotic diversity gain is zero regardless of the spatial diversity might be offered by the relay selection policy, and the multipath diversity might be offered by the single carrier system. However, the full diversity gain of HDR is achievable.

4) We verify our new expressions for lower bound on the outage probabilities and their corresponding asymptotic diversity gains via simulations. We showcase the impact of the number of SRs and the number of PUs on the outage probability. We conclude that the outage probability of CogFDR decreases with increasing number of SRs, and increases with increasing the number of PUs. Interestingly, we notice that the outage probability of CogFDR decreases as the ratio of the maximum transmit power constraint at the SR to the maximum transmit power at the SS decreases.

5) We compare the outage performance between CogHDR with the target data rate 2RT and CogFDR with the target data rate RT, considering that the SS and the SRs transmit using two different channels in CogHDR, while the transmission in CogFDR only require one channel. We conclude that CogFDR is a good solution for the systems that operate at low to medium SNRs, while CogHDR is more favorable to those operate in the high SNRs.

The rest of the paper is organized as follows. In Section II, we present the system and the channel model for cooperative CP-SC CogFRN and cooperative CP-SC CogHRN with AF relaying. Distributions of the SNRs are derived in Section III. The asymptotic description is given in Section IV. The outage probability and the corresponding asymptotic outage probability of CogFRN and CogHRN with several relay selection policies are derived in Sections V and VI, respectively. Simulation results are provided in Section VII. Conclusions are drawn in Section VIII.

Notations: The superscript $\mathbf{H}$ denotes complex conjugate transposition, $E\{\cdot\}$ denotes expectation, and $CN(\mu, \sigma^2)$ denotes the complex Gaussian distribution with mean $\mu$ and variance $\sigma^2$. The $F_{\phi}(\cdot)$ and $f_{\phi}(\cdot)$ denote the CDF of the random variable (RV) $\phi$ for FDR and HDR, respectively. Also, $F_{\phi}(\cdot)$ and $f_{\phi}(\cdot)$ denote the PDF of $\phi$ for FDR and HDR, respectively. The binomial coefficient is denoted by $\binom{n}{k}$.

II. SYSTEM AND CHANNEL MODEL

We consider a cooperative spectrum sharing network consisting of L PU-receivers $(PU_1, \ldots, PU_L)$, a single SS, a single secondary destination (SD), and a cluster of $K$ SRs $(SR_1, \ldots, SR_K)$ as shown in Fig. 1, where the solid and the dashed lines represent the secondary channel and the interference channel, respectively. The CP-SC transmission is used in this network. Among the $K$ SRs, the best SR which fulfills
the relay selection criterion is selected to forward the transmission to the SD using the AF relaying protocol. Similar to the model used in [8], [33], and [34], we focus on the coexistence of long-range primary system such as IEEE 802.22, and short range CR networks, such as WLANs, D2D networks and sensor networks. In this case, the primary to secondary link is severely attenuated to neglect the interference from the PU transmitters to the SU receivers. We also assume there is no direct link between the SS and the SRs due to long distance and deep fades. In this network, we make the following assumptions for the channel models, which are practically valid in cooperative spectrum sharing networks.

Assumption 1: For the secondary channel, the instantaneous sets of channel impulse responses (CIRs) from the SS to the kth SR and from the kth SR to the SS composing of $N_{1,k}$ and $N_{2,k}$ multipath channels, are denoted as $g_{N_{1,k}} = [g_{0}^{k}, ..., g_{N_{1,k}-1}^{k}] \in \mathbb{C}^{N_{1,k} \times 1}$ and $g_{N_{2,k}} = [g_{0}^{k,d}, ..., g_{N_{2,k}-1}^{k,d}] \in \mathbb{C}^{N_{2,k} \times 1}$, respectively. For the primary channel, we assume perfect CSI from the SS to the lth PU link and from the kth SR to the lth PU link, which can be obtained through direct feedback from the PU [35], indirect feedback from a third party, and periodic sensing of pilot signal from the PU [36]. The instantaneous sets of CIRs from the SS to the lth PU (PU$l$) and from the kth SR to the lth PU composing of $N_{3,l}$ and $N_{4,k,l}$ multipath channels, are denoted as $f_{N_{3,l}} = [f_{0}^{l}, ..., f_{N_{3,l}-1}^{l}] \in \mathbb{C}^{N_{3,l} \times 1}$ and $f_{N_{4,k,l}} = [f_{0}^{l,k}, ..., f_{N_{4,k,l}-1}^{l,k}] \in \mathbb{C}^{N_{4,k,l} \times 1}$, respectively.

All channels are composed of independent and identically distributed (i.i.d) complex Gaussian RVs with zero means and unit variances. The maximum channel length $N_{\text{max}}$ is assumed to be shorter than the CP length, denoted by $N_{\text{CP}}$, to restrain the interblock symbol interference (IBSI) and intersymbol interference (ISI) in single carrier transmission [31]. Accordingly, the path loss components from the SS to the kth SR, from the kth SR to the SD, from the SS to the PU$l$, and from the kth SR to the PU$l$ are defined as $a_{1,k}, a_{2,k}, a_{3,l},$ and $a_{4,k,l}$, respectively.

Assumption 2: For underlay spectrum sharing, the peak interference power constraint at the lth PU is denoted as $I_{l0}$.

Also due to hardware limitations, the transmit power at the SS and the SRs are restricted by the maximum transmit power constraints $P_{T}$ and $P_{R}$, respectively.

A. CogFRN

In the full-duplex mode, each SR is equipped with a single transmit and a single receive antenna, which enable full-duplex transmission in the same frequency band at the expense of introducing residual loop interference. The SS and the SR transmit to the SD in the same time slot. As such, the PUs suffer interference from the SS and the SRs concurrently. Similar as [25], we simply assume that the maximum interference inflicted on the PUs by the SS or the SRs are set to be a half of the total peak interference power constraint at the PUs ($\frac{1}{2}P_{T} = Q$), where $Q$ is the peak interference constraint.

Therefore, the transmit power at the SS and the kth SR are given by

$$P_{S}^{F} = \min \left( \frac{Q}{y_{1}}, P_{T} \right),$$

$$P_{R,k}^{F} = \min \left( \frac{Q}{y_{k}}, P_{R} \right),$$

where

$$y_{1} \triangleq \max_{l=1,...,L} \left\{ a_{3,1}\|f_{l,1}^{1}\|^{2} \right\},$$

and

$$y_{k} \triangleq \max_{l=1,...,L} \left\{ a_{4,k,l}\|f_{l,k}^{1}\|^{2} \right\}.$$
relay is modeled as a complex Gaussian random variable with
zero mean and variance $\sigma_n^2$; i.e., $\mathbf{n}_{sk} \sim \mathcal{CN}(0, \sigma_n^2).$
In AF relaying, the SRs are unable to distinguish between
the signal from the SS and the residual loop interference
signals at the SRs. Thus, both signals are amplified and for-
warded to the SD. The received signal at the SD via the $kth$
SR is given by

$$y_{r,d} = \sqrt{\alpha_{2,k}} g_{N2,k} \mathbf{G}_k \mathbf{y}_{r,k} + \mathbf{n}_{r,d},$$

where $g_{N2,k}$ is the right circulant matrix formed by
$[g_{N2,k}^T, \mathbf{0}_{1 \times (N_2 - N_{2,k})}]^T \in \mathbb{C}^{N_2 \times 1}$, $\mathbf{G}_k \triangleq g_k^H \mathbf{I}_{N_k}$ is the relay
gain matrix for the $k$th SR, and $\mathbf{n}_{r,d} \sim \mathcal{CN}(0, \sigma_n^2).$

respectively, where $\mathbf{G}_k \triangleq g_k^H \mathbf{I}_{N_k}$ is the relay gain matrix for
the $k$th SR, and $g_k^H \triangleq \frac{p_{R,k}}{p_{k}}$. Therefore, the

$$y_{He2e} = \frac{\gamma_{k}^{x,k} \gamma_{k}^{d}}{\gamma_{H}^{x} + \gamma_{H}^{d} + 1} \leq \min\left(\gamma_{k}, \frac{\gamma_{k}^{x,k} \gamma_{k}^{d}}{\gamma_{H}^{x} + \gamma_{H}^{d} + 1}\right),$$

where the SNR from the SS to the $k$th SR is denoted
as $\gamma_{H}^{x} \triangleq x_k y_k^H$ with $\gamma_{H}^{x} \overset{\Delta}{=} \frac{p_{k}^{H}}{\sigma_n^2}$
and the SNR from the $k$th SR to
the SD is denoted as $\gamma_{k}^{d} \triangleq w_k y_k^H$ with $\gamma_{k}^{d} \overset{\Delta}{=} \frac{p_{R,k}^H}{\sigma_n^2}$.

### III. DISTRIBUTIONS OF SNR AND SINR

In this section, we first derive the CDFs and PDFs of the
$Y_1$ and $Y_2$ based on the Definition 1 and Definition 2 in the following.
We then utilize these CDFs and PDFs to facilitate the
derivations of CDFs of $\gamma_{He}^{x,k}, \gamma_{He}^{x,k}$ and $\gamma_{He}^{y,k}.$

**Definition 1:** The PDF and the CDF of a RV $X$ distributed
as a gamma distribution with shape $N$ and scale $\alpha$ are given,
respectively, as

$$f_X(x) = \frac{1}{\Gamma(N)\alpha^N} x^{N-1} e^{-x/\alpha},$$

and $F_X(x) = \left(1 - e^{-x/\alpha} \sum_{l=0}^{N-1} \frac{1}{l!}(x/\alpha)^l\right) U(x),$

where $U(\cdot)$ denotes the discrete unit step function. In the sequel,
the RV $X$ distributed according to a gamma distribution with shape $N$ and scale $\alpha$ is denoted by $X \sim \Gamma(N, \alpha).$

Here, shape $N$ is positive integer.

**Definition 2:** Let $X_i \sim \Gamma(N_i, 1)$, then the CDF and the
PDF of a RV $X_{\text{max}} \overset{\Delta}{=} \max\{X_1, X_2, \ldots, X_L\}$ are given,
respectively, as

$$F_{X_{\text{max}}}(x) = 1 + \sum_{L_{ji} \cup \{a_i\} = N} \left[\sum_{L_{ji} \cup \{a_i\} = N} \left(\sum_{j=0}^{L} \sum_{i=0}^{N_a-1} \frac{1}{i!} L_{ji}^{i} U(x) - bx U(x)\right)\right].$$

where

$$\sum_{L_{ji} \cup \{a_i\} = N} \left(\sum_{j=0}^{L} \sum_{i=0}^{N_a-1} \frac{1}{i!} L_{ji}^{i} U(x) - bx U(x)\right)$$

$\overset{\Delta}{=} \sum_{j=0}^{L} \sum_{i=0}^{N_a-1} \frac{1}{i!} L_{ji}^{i} U(x) - bx U(x),$
gamma distributions with shapes $N_{1,k}$, $N_{2,k}$, $N_{3,l}$, and $N_{4,k,l}$, respectively, and scale 1. Also, $|h_k|^2$ is distributed as a gamma distribution with shape 1 and scale 1. We have also defined the two RVs $X_k \sim \alpha_{1,k} \text{Gamma}(N_{1,k}, \alpha_{1,k})$ and $Y_1 \triangleq \max \{\alpha_3, ||r_{N_1,k}^l||^2\}$. For notational purposes, in the sequel, we have defined the normalized powers $\tilde{y}_Q \triangleq Q\gamma$, $\tilde{y}_R \triangleq P_T\gamma$, and $\tilde{y}_{R} \triangleq P_{R}\gamma$, with $\gamma \triangleq \frac{1}{2}$. According to the distribution of $||r_{N_1,k}^l||^2$, the CDF and the PDF of $Y_1$ are given by

$$F_{Y_1}(x) = 1 + \sum_{L,j,\{N_{1,l}\},\{\alpha_{3,l}\}} \left[ x^e^{-\tilde{y}_1x}U(x) \right],$$

and

$$f_{Y_1}(x) = \sum_{L,j,\{N_{1,l}\},\{\alpha_{3,l}\}} e^{-\tilde{y}_1x} \left[ x^d^{-1}U(x) - \tilde{y}_1x^eU(x) \right],$$

where $\tilde{y}\triangleq \sum_{l=1}^{L} \tilde{y}_l$ and $\tilde{y}_1 \triangleq \sum_{l=1}^{L} \frac{1}{\alpha_{3,l}}$.

A. CogFRN

From the definition of the SNR from the SS to the kth SR $Y^k_F \triangleq \min(Q/Y_1, P_T)X_k\gamma$, we have the following CDF of $Y^k_F$ as

$$F_{Y^k_F}(y) = 1 - e^{-\frac{y}{\alpha_1 \gamma}} \sum_{l=0}^{N_{1,k}-1} \frac{1}{l!} \left( \gamma \alpha_{1,k} \gamma_l \right)^l \frac{(\gamma/\tilde{y}_Q)^{N_{1,k}}}{(\alpha_{1,k})^l N_{1,k}^{\alpha_{1,k}}} \Gamma(N_{1,k}) \times \sum_{L,j,\{N_{1,l}\},\{\alpha_{3,l}\}} \left[ \Gamma(N_{1,k} + \tilde{y}_1 \frac{\alpha_{1,k} \alpha_{1,l} \tilde{y}_F}{\alpha_{1,l} \gamma_l} + \mu_T \tilde{y}_1) \right] \left( \gamma_{\alpha_{1,l} \gamma_l} + \tilde{y}_1 \right)^{N_{1,k}+\tilde{y}_1},$$

where $\mu_T \triangleq \frac{Q}{\gamma}$ and $\Gamma(\cdot, \cdot)$ denotes the incomplete gamma function.

Proof: See Appendix A.

B. CogHRN

In cooperative CP-SC CogHRN, we have $Y^k_H \triangleq \min(2Q/Y_1, P_T)X_k\gamma$. We derive the CDF of $Y^k_H$ as

$$F_{Y^k_H}(y) = 1 - e^{-\frac{y}{\alpha_1 \gamma}} \sum_{l=0}^{N_{1,k}-1} \frac{1}{l!} \left( \gamma \alpha_{1,k} \gamma_l \right)^l \frac{(\gamma/2\tilde{y}_Q)^{N_{1,k}}}{(\alpha_{1,k})^l N_{1,k}^{\alpha_{1,k}}} \Gamma(N_{1,k}) \times \sum_{L,j,\{N_{1,l}\},\{\alpha_{3,l}\}} \left[ \Gamma(N_{1,k} + \tilde{y}_1 \frac{\alpha_{1,k} \alpha_{1,l} \tilde{y}_F}{\alpha_{1,l} \gamma_l} + 2\mu_T \tilde{y}_1) \right] \left( \gamma_{\alpha_{1,l} \gamma_l} + \tilde{y}_1 \right)^{N_{1,k}+\tilde{y}_1}.$$
asymptotic CDF of $\gamma_{p}^{k,j}$ as
\[
\mathbb{P}_{\gamma_{p}^{k,j}}(\gamma) = 1 - e^{-\frac{\gamma}{\tilde{\gamma}}}
\]
\[= -\frac{\gamma}{\mu_{T}} \sum_{L,d,r,N_{a1},a_{4}} \Gamma \left( \tilde{d} + 1, \left( \frac{\gamma}{\mu_{T} + \tilde{\beta}_{2}} \right)^{\tilde{d}+1} \right).\] (25)

The derivation of (24) and (25) are similar to those provided in Appendix A.

B. CogHRN

Different from the approach used in deriving the asymptotic e2e-SINR of CogFRN, in CogHRN, we use the first order expansion for the CDFs of $\gamma_{H}^{k}$ and $\gamma_{H}^{k,d}$ to derive the asymptotic e2e-SINR of CogHRN.

1) Asymptotic SNR From the SS to the kth SR: When $\gamma_{T} \to \infty$ and $\gamma_{O} \to \infty$, an asymptotic expression of $F_{X_{k}}(\gamma_{T})$ is derived by applying [38, eq. (1.211.1)] and [38, eq. (3.354.1)]
\[
F_{X_{k}}(\gamma_{T}) \approx \frac{1}{\Gamma(N_{a1} + 1)} \left( \frac{\gamma}{\alpha_{1} \gamma_{T}} \right)^{N_{a1}}. \tag{26}
\]

The asymptotic CDF of $\gamma_{H}^{s,k}$ is derived as
\[
F_{\gamma_{H}^{s,k}}(\gamma) = \frac{1}{\Gamma(N_{a1} + 1)} \left( \frac{\gamma}{\alpha_{1} \gamma_{T}} \right)^{N_{a1}} \left[ 1 - e^{-\frac{2\mu_{T} \gamma}{\alpha_{3}}} \sum_{j=0}^{N_{a1}-1} \frac{1}{j!} \left( \frac{2\mu_{T}}{\alpha_{3}} \right)^{j} \right].
\]

2) Asymptotic SNR From the kth SR to the SD: When $\gamma_{R} \to \infty$ and $\gamma_{O} \to \infty$, the asymptotic CDF of $\gamma_{H}^{k,d}$ is derived as
\[
F_{\gamma_{H}^{k,d}}(\gamma) = \frac{1}{\Gamma(N_{a2} + 1)} \left( \frac{\gamma}{\alpha_{2} \gamma_{R}} \right)^{N_{a2}} \left[ 1 - e^{-\frac{2\mu_{R} \gamma}{\alpha_{4}}} \sum_{j=0}^{N_{a2}-1} \frac{1}{j!} \left( \frac{2\mu_{R}}{\alpha_{4}} \right)^{j} \right].
\]

Having (27) and (28) for the CDFs of $\gamma_{H}^{s,k}$ and $\gamma_{H}^{k,d}$ in closed-form, respectively, we derive the lower bound on the outage probability of CogHRN in Section VI.

V. OUTAGE PROBABILITY OF COGFRN

In this section, we derive the expression for the lower bound on the outage probabilities of CogFRN with various relay selection policies based on the max-min criterion, partial relay selection criterion, and maximum interference criterion. We then derive the corresponding asymptotic outage probabilities to observe the diversity gains of the three selection policies.

A. CogFRN With MM

Compared with the conventional MM policy in CogHRN, the MM policy in CogFRN takes into account the loop interference. Let $k_{MM}$ be the selected relay based on the max-min criterion. The employed relay selection is mathematically given by
\[
k_{MM} = \operatorname{arg}_{k=1,...,K} \min \left( \frac{\gamma_{F,k}^{s,k}}{\gamma_{F}^{T,k} + 1}, \frac{\gamma_{F,k}^{d,k}}{\gamma_{F}^{T,k}} \right). \tag{29}
\]

1) Outage Probability: The lower bound on the outage probability of CogHRN at a given threshold $\eta_{F}$ is given by
\[
\mathbb{P}_{\text{out}}^{\text{MM}}(\eta_{F}) = \int_{0}^{\infty} \left( 1 - \left( 1 - F_{\gamma_{F,k}^{s,k}}(\eta_{F}) \right) \left( 1 - F_{\gamma_{F,k}^{d,k}}(\eta_{F}) \right) \right) f_{\gamma_{T}}(\gamma) d\gamma. \tag{30}
\]

Theorem 1: The lower bound on the outage probability of CogFRN with MM policy is derived as
\[
\mathbb{P}_{\text{out}}^{\text{MM}}(\eta_{F}) = \int_{0}^{\infty} \left[ \prod_{i=0}^{N_{a1}-1} \sum_{j=0}^{N_{a1}-1} \frac{1}{j!} \left( \frac{2\mu_{T}}{\alpha_{3}} \right)^{j} \right] \left[ \prod_{m=0}^{N_{a1}+j-1} \sum_{m=0}^{N_{a1}+j-1} \frac{1}{m!} \left( \frac{2\mu_{R}}{\alpha_{4}} \right)^{m} \right] \left[ \Gamma \left( N_{a2} + \frac{\eta_{F}}{\alpha_{2} \gamma_{R}} \right) \right] \left[ \Gamma \left( N_{a2} + \frac{\eta_{F}}{\alpha_{2} \gamma_{R}} \right) \right] \left[ \sum_{L,d,r,N_{a1},a_{4}} \int_{0}^{\gamma_{T}} dy \right] \left[ \sum_{L,d,r,N_{a1},a_{4}} \frac{e^{-\frac{\gamma_{T}}{\tilde{\gamma}}}}{(\gamma_{T})^{N_{a1}+j-1}} \right] \left[ \sum_{L,d,r,N_{a1},a_{4}} \frac{e^{-\frac{\gamma_{R}}{\tilde{\gamma}}}}{(\gamma_{R})^{N_{a2}+j-1}} \right] d\gamma.
\]

where
\[
\Pi_{1}(i,t) = \frac{1}{i!} \left( \frac{\eta_{F}}{\alpha_{1} \gamma_{T}} \right)^{i} e^{-\frac{\eta_{F}}{\alpha_{1} \gamma_{T}}}, \tag{32}
\]
\[ \Pi_2(m, n, h) = \frac{\left( \eta F_{\bar{y}Q} \right)^{N_1,k}}{(\alpha_1,k)^{N_1,k}} \Gamma(\eta F_{\bar{y}Q}) \left( \frac{\eta F}{\alpha_1,k \bar{y}Q} \right)^{h+1-N_1,k} \right) \cdot \psi \left( h+1, h+2-N_1,k \right) \] (34).
\[ \mathbb{P}_{\text{MI}}^\text{out}(\eta_F) = \int_0^\infty \left\{ 1 - \left\{ \frac{y}{\gamma_R} \sum_{i=0}^{N_k-1} \Pi_1(i, t) \left( \frac{\eta_F}{\alpha_k \gamma_T} + \frac{y}{\gamma_Q} \right)^{-t-1} \Gamma(t+1) + \frac{1}{\gamma_R} \sum_{m=0}^{N_k-1} \sum_{n=0}^{N_1-1} \Pi_2(m, n, h) \Pi_3 \left( h, \frac{\eta_F}{\alpha_k \gamma_T} + \frac{1}{\gamma_R} \right) \right\} e^{-\gamma_T} \right\} K \left( 1 + \sum_{i=0}^{N_k-1} e^{-\gamma_T} \right) K^{-1} \right\} dy \]
Substituting (21) and (22) into (51), we can easily derive the lower bound on the outage probability of CogHRN with the PS policy.

\[
P_{PS}(\eta_H) = 1 - \left( 1 - F_{\gamma_H}^{\alpha,1}(\eta_H) \right)^{K} \left( 1 - F_{\gamma_H}^{\alpha,2d}(\eta_H) \right).
\]

Substituting (21) and (22) into (51), we can easily derive the lower bound on the outage probability of CogHRN with the PS policy.

\[
P_{PS}(\eta_H) = 1 - \left( 1 - F_{\gamma_H}^{\alpha,1}(\eta_H) \right)^{K} \left( 1 - F_{\gamma_H}^{\alpha,2d}(\eta_H) \right).
\]

**Lemma 2:** The diversity gain with the PS policy is \( \min(\eta_1, \eta_2) \) as \( \gamma_H \to \infty \).

**Proof:** Based on (27) and (28), we can easily see that

\[
P_{PS}^{\infty}(\eta_H) \approx F_{\gamma_H}^{\alpha,1}(\eta_H)^K + F_{\gamma_H}^{\alpha,2d}(\eta_H)
\]

\[
\approx \begin{cases} 
  d_3^K \left( \frac{\eta_H}{\gamma_H} \right)^{KN_1}, & \text{if } N_1 < N_2, \\
  d_6^K \left( \frac{\eta_H}{\gamma_H} \right)^{KN_2}, & \text{if } N_2 < N_1, \\
  (d_3 + d_6)^K \left( \frac{\eta_H}{\gamma_H} \right)^{KN}, & \text{if } N = N_1 = N_2.
\end{cases}
\]

Thus, the diversity gain is \( \min(\eta_1, \eta_2) \).

We can readily see that the number of PUUs has no effect on the diversity gain with the MM and the PS policies.

Table I highlights the required CSI for the three relay selection strategies of CogFDR and CogHDR.

**VII. Simulation Results**

In this section, we present numerical results to verify our new analytical results for three different relay selection policies in cooperative CP-SC spectrum sharing systems with the link level simulation. We assume the symbol block size as \( N_i = 512 \) and CP length as \( N_{CP} = 16 \). For the purpose of comparison, we set the target data rate as \( R_T = 1 \) bit/s/Hz, thus the fixed SNR threshold for CogFRN is denoted as \( \gamma_H = 10 \). However, in CogHDR, two different channels are needed for CP-SC transmission. We assume that both the SS and the SRs use half of the resource, therefore a fixed SNR threshold for CogHDR is denoted as \( \gamma_H = 2R_T - 1 \). In order to examine the effects of power scaling on the outage probability, in the simulations we set \( \gamma_H = \rho \gamma_T, \gamma_H = \mu \gamma_T, \) and \( \gamma_H = \mu_k \gamma_T \). The figures highlight the accuracy of our derived closed-form expressions for the relay selection policies. In all the figures, we assume \( \{N_3, \alpha_3\} = (2, 0.5) \) and \( \{N_4, \alpha_4\} = (3, 0.3) \).

Fig. 2 shows the outage probability of CogFRN for various numbers of relays and different relay selection policies. The exact plots with MM, PS, and MI relay selection policies are numerically evaluated using (31), (39), and (42). The asymptotic outage probabilities are plotted from (35), (40), and (45). First, we observe error floors in the high SNR with zero outage diversity gain, which is due to the dominant effects of the residual loop interference. Second, for the same number of relays, for example \( K = 6 \), relay selection policy MM outperforms PS, and PS outperforms MI over all SNR values. The outage probabilities with MM policy and PS policy improve...
with increasing the number of SRs, while the outage probability with MI policy is not significantly improved by deploying more SRs. Interestingly, the performance gaps between each selection policy increase as the number of SRs increases.

In Fig. 3, we examine the outage probability of CogFRN for various numbers of PUs and different relay selection policies. It is easy to note that increasing the number of PUs deteriorates the outage performance of CogFRN since the secondary network has less chance to share the spectrum of the primary network when the number of PUs is large.

In Fig. 4, we compare the outage probability of CogFRN and CogHRN at the same target data rate under different relay selection policies. Interestingly, we notice that: 1) Compared with CogHRN, CogFRN sacrifice the outage probability to achieve the potential higher spectral efficiency; and 2) CogHRN overcomes the outage floors of CogFRN in the high SNRs. This is due to the fact that the dominating effect of residual loop interference is removed in CogHRN.

In Fig. 5, we examine the impact of the ratio between the peak interference power constraint at the PU and the maximum transmit power constraint at the SS ($Q/PT$) on the outage performance of CogFRN with the MM relay selection policy. We see that the outage probability for the same relay selection policy improves with a more relaxed peak interference power constraint at the PU. The higher ratio between the peak interference power constraint at the PU and the maximum transmit power constraint at the SS, the lower error floors and the bigger gaps among these three policies can be achieved. It is readily observed that the diversity gain is zero regardless of $\mu_T$ in the high SNR regime.

In Fig. 6, we show the outage probability with FDR and HDR as a function of $\rho$, which is the ratio between $\gamma_R$ and $\gamma_T$. For the same relay transmission mode and the same relay selection policy, the parallel slopes illustrate that the diversity gain is unrelated to $\rho$. Interestingly, we observe that as $\rho$ increases, a better outage performance is achieved in CogHRN, while a...
worse outage performance in CogFRN, and the crossover point between full-duplex and half-duplex moves to the left. This is due to the fact that with $\rho$ increases, $\gamma_T$ increases, which results in the enhancement of the second hop transmission in CogHRN. However, due to increased residual loop interference with increasing $\rho$, the adverse effect of the residual loop interference grows with increasing the transmit power of SR.

In Fig. 7, we examine the outage probability with FDR with various relay selection policies and $\rho$. Similar phenomenon in CogFRN is observed as Fig. 6. As $\rho$ decreases, the outage probability with the PS policy and the MI policy degrade. This is because the residual loop interference is a detrimental characteristic of FDR, which is shown in (29), (37), and (41). We define $\gamma_T < 12$ dB as the SNR dominant region, and $\gamma_T > 25$ dB as the residual loop interference dominant region. In the diversity achievable SNR dominant region, we observe that the outage probability decreases as increasing $\gamma_T$. In the residual loop interference dominant region, we observe the zero diversity gain, which restricted the decreasing trend of outage probability.

VIII. CONCLUSION

We have examined the effects of residual loop interference in cooperative CP-SC spectrum sharing with FDR. The lower bound on the outage probabilities and asymptotic outage probabilities for the MM policy requiring global CSI, as well as the PS and the MI policies requiring partial CSI have been derived and quantitatively compared. Interestingly, we observe that the diversity gain results from spatial diversity and multipath diversity can be achieved in the SNR dominant region, whereas the diversity gain lost in the residual loop interference dominant region. For comparison purposes, the lower bound on the outage probabilities and the corresponding asymptotic outage probabilities of cooperative CP-SC spectrum sharing with HDR have been derived for each of the relay selection policies. Our results show that CogFDR is a good solution to achieve the spectral efficiency and bearable outage probability for the systems that operate at low to medium SNRs, while CogHDR is more favorable to those operate in the high SNRs.

APPENDIX A

DETAILED DERIVATION OF (20)

We start from the definition of the CDF of $\gamma_F^{r,k}$, which is given by

$$F_{\gamma_F^{r,k}}(\gamma) = \Pr(\min(Q/Y_1, P_T)X_k\tilde{y} \leq \gamma)$$

$$= F_{X_k}(\gamma/\gamma_T)\mathbb{E}_{Y_1}(\mu_T) + \int_{\mu_T}^{\infty} \mathbb{E}_{X_k}(\gamma/\gamma_T)dy,$$  \hspace{1cm} (A.1)

We use the integration by parts to solve $I_1$ of (A.1), which is given by

$$I_1 = \mathbb{E}_{X_k}(\gamma/\gamma_T)\mathbb{E}_{Y_1}(\gamma/\gamma_T)\int_{\mu_T}^{\infty} \mathbb{E}_{Y_1}(\gamma/\gamma_T)dy + \int_{\mu_T}^{\infty} \mathbb{E}_{X_k}(\gamma/\gamma_T)dy.$$  \hspace{1cm} (A.2)

Substituting (A.2) into (A.1), we first obtain

$$F_{\gamma_F^{r,k}}(\gamma) = \mathbb{E}_{X_k}(\gamma/\gamma_T)$$

$$- \sum_{L_{ji},\{\alpha_{ji}\}} \frac{\gamma}{\gamma_T} \left[ \int_{\mu_T}^{\infty} \mathbb{E}_{X_k}(\gamma/\gamma_T)dy \right] dy.$$  \hspace{1cm} (A.3)

Then using [38, eq. 3.351.2] and the PDF of $X_k$, the closed-form expression for the CDF of $\gamma_F^{r,k}$ can be derived as (20).
APPENDIX B

Detailed Derivation of (31)

Based on (30), the outage probability with MM policy is given as

$$\mathbb{P}_{\text{MM}}^\text{out}(\eta F) = \sum_{k=1}^{K} \left[ \int_{-\infty}^{\infty} \left( 1 - F_{\gamma_F}^{\text{MM}}(\eta F) \right) f_{\gamma_F}(y) dy \right] \left( 1 - F_{\gamma_F}^{\text{MM}}(\eta F) \right) f_{\gamma_F}(y) dy, \quad (B.1)$$

where $\sigma_F^k | y > \mu_R = \frac{\gamma_F^k}{\mu_R^k + 1}$, $\gamma_F^k | y > \mu_R = \frac{\gamma_0}{\gamma} W_k$, $\sigma_F^k | y \leq \mu_R = \frac{\gamma_0}{\gamma} W_k$, and $\gamma_F^k | y \leq \mu_R = W_k Y_R$.

In (E.1), $F_{\gamma_F^k | y > \mu_R}(\eta F)$ and $F_{\gamma_F^k | y \leq \mu_R}(\eta F)$ are presented as

$$F_{\gamma_F^k | y > \mu_R}(\eta F) = \int_{0}^{\infty} F_{\gamma_F^k(y(x+1))} f_{\gamma_F^{\text{MM}} | y > \mu_R}(x) dx,$$

and $F_{\gamma_F^k | y \leq \mu_R}(\eta F) = \int_{0}^{\infty} F_{\gamma_F^k(y(x+1))} f_{\gamma_F^{\text{MM}} | y \leq \mu_R}(x) dx.$

(B.2)

respectively.

Based on the derivation of $W_k, R_k, \gamma_F^k, \text{and } Y_k$, we derive $\mathbb{P}_{\text{MM}}^\text{out}(\eta F)$.

APPENDIX C

Detailed Derivation of (36)

Similar as the analysis in Appendix B, the first term $R_1$ is evaluated as

$$R_1 = \sum_{i=0}^{N_1-1} \frac{1}{i!} \left( \frac{\gamma}{\alpha_1} \right)^i \times \left[ \frac{1}{\rho} \left( 1 + \frac{\gamma}{\alpha_1} \right)^{-1-i} \Gamma(i+1) - \sum_{L_d, [N_d],[\alpha_d]} \mu_T^{\tilde{d}-d} \tilde{\omega}_{i-d} \tilde{P}_2 \right]$$

$$\times \left[ \sum_{r=0}^{\tilde{d}} \sum_{w=0}^{r} \gamma \left( \tilde{d} + 1, \frac{\mu_T}{\rho}, \frac{1}{\mu_T} \right) \Gamma(wi + 1) \gamma_{wi + 1, wi + 1} \right.$$

$$- \tilde{d}, \left( 1 + \frac{\gamma}{\alpha_1} \right) \mu_T \tilde{P}_2 \right)$$

$$- \sum_{r=0}^{\tilde{d}+1} \sum_{w=0}^{r} \gamma \left( \tilde{d} + 1, \frac{\mu_T}{\rho}, \frac{1}{\mu_T} \right) \Gamma(wi + 2) \gamma_{wi + 2, wi + 1} \right.$$

$$- \tilde{d}, \left( 1 + \frac{\gamma}{\alpha_1} \right) \mu_T \tilde{P}_2 \right). \quad (C.1)$$

where $wi \equiv w + i$, $\gamma(\sigma, \tau, \varepsilon) = \sigma! e^{-\tilde{\omega}_{i-d}(\tilde{\omega})} \tilde{\omega}_{i-d}^{\tilde{\omega}_{i-d}^{\tilde{\omega}_{i-d}-\mu_T \tilde{P}_2}}$.

Applying [38, eq. 9.211.4] and [38, eq. 8.352.2], we derive $R_2$ as

$$R_2 = \sum_{L_d, [N_d],[\alpha_d]} \sum_{m=0}^{N_1} \sum_{n=0}^{N_1} \Phi(\mu_T)$$

$$\times \left\{ \begin{array}{l}
\frac{1}{\rho} \tilde{p}_{\tilde{r} + N_1 - j}(N_1 + n + 1, N_1 + n + 2 - j, a_{\mu_T \tilde{p}_2}) \\
\sum_{R_d, [N_d],[\alpha_d]} \sum_{r=0}^{\tilde{d}} \sum_{j=0}^{\tilde{d}} \gamma \left( \tilde{d}, \frac{\mu_T}{\rho}, \frac{1}{\mu_T} \right) \\
\times e^{1} \sum_{l=1}^{\tilde{d}+1} c_i \left( a_{\mu_T \tilde{p}_2} \right)^{-l_1} \\
\times \Phi(\mu_T) \\
\end{array} \right\}.$$
APPENDIX D

DETAILED DERIVATION OF (39)

Based on (37), the outage probability with PS policy is given as

\[
P_{\text{out}}^{\text{PS}}(\eta_F) = \int_{\mu_R}^{\infty} \left(1 - \left(1 - F_{\tilde{\eta}_F}^{\text{PS}} \left| \gamma > \mu_R (\eta_F) \right. \right) \right) f_{\tilde{Y}_k}(y) dy\]

\[
+ \int_{0}^{\mu_R} \left(1 - \left(1 - F_{\tilde{\eta}_F}^{\text{PS}} \left| \gamma < \mu_R (\eta_F) \right. \right) \right) f_{\tilde{Y}_k}(y) dy.
\]

\[(D.1)\]

Thus, \(P_{\text{out}}^{\text{PS}}(\eta_F)\) can be derived by using the distribution of \(W_k, R_k, \gamma_F^{k,i}, \) and \(Y_k\).

APPENDIX E

DETAILED DERIVATION OF (42)

Based on (41), the outage probability with MI policy is given as

\[
P_{\text{out}}^{\text{MI}}(\eta_F) = \int_{\mu_R}^{\infty} \left(1 - \left(1 - F_{\tilde{\eta}_F}^{\text{MI}} \left| \gamma > \mu_R (\eta_F) \right. \right) \right) f_{\tilde{Y}_{k_{\text{MI}}}}(y) dy\]

\[
+ \int_{0}^{\mu_R} \left(1 - \left(1 - F_{\tilde{\eta}_F}^{\text{MI}} \left| \gamma < \mu_R (\eta_F) \right. \right) \right) f_{\tilde{Y}_{k_{\text{MI}}}}(y) dy.
\]

\[(E.1)\]

where \(F_{\tilde{\eta}_F}^{\text{MI}} \left| \gamma > \mu_R \right. = \frac{e^{\frac{-\gamma}{\mu_R}}}{\frac{\gamma}{\mu_R} R_k + 1}\) and \(F_{\tilde{\eta}_F}^{\text{MI}} \left| \gamma < \mu_R \right. = \frac{e^{\frac{\gamma}{\mu_R}}}{\frac{\gamma}{\mu_R} R_k + 1}\), and \(Y_{k_{\text{MI}}} = \max_{k=1, \ldots, K} \{Y_k\}\).

Thus, \(P_{\text{out}}^{\text{MI}}(\eta_F)\) can be derived by using the distribution of \(W_k, R_k, \gamma_F^{k,i}, \) and \(Y_k\).

REFERENCES

Yansha Deng (M’16) received the Ph.D. degree in electrical engineering from the Queen Mary University of London, U.K., in 2015. She is currently the Post-Doctoral Research Fellow with the Department of Informatics, King’s College London, U.K. Her research interests include massive MIMO, HetNets, molecular communication, cognitive radio, cooperative networks, and physical layer security. She was a recipient of the Best Paper Award in ICC 2016. She has served as a TPC Member for several IEEE conferences such as IEEE GLOBECOM and ICC.

Kyeong Jin Kim (SM’11) received the M.S. degree from the Korea Advanced Institute of Science and Technology, in 1991, and the M.S. and Ph.D. degrees in electrical and computer engineering from the University of California at Santa Barbara, Santa Barbara, CA, USA, in 2000. From 1991 to 1995, he was a Research Engineer with the Data Transmission and Networking Laboratory, University of California at Santa Barbara. He joined the Data Transmission and Networking Laboratory, University of California at Santa Barbara. He joined the Nokia Research Center and Nokia Inc., Dallas, TX, USA, as a Senior Research Engineer, where he was an L1 Specialist from 2005 to 2009. From 2010 to 2011, he was an Invited Professor with Inha University, Incheon, South Korea. Since 2012, he has been a Senior Principal Research Staff with Mitsubishi Electric Research Laboratories, Cambridge, MA, USA. His research has been focused on the transceiver design, resource management, scheduling in the cooperative wireless communications systems, cooperative spectrum sharing systems, device-to-device communications, secrecy systems, and GPS systems.

Trung Q. Duong (S’05–M’12–SM’13) received the Ph.D. degree in telecommunications systems from the Blekinge Institute of Technology, Sweden, in 2012. Since 2013, he has been a Lecturer (Assistant Professor) with Queen’s University Belfast, U.K. His current research interests include physical layer security, energy-harvesting communications, and cognitive relay networks. He has authored or co-authored 190 technical papers published in scientific journals and presented at international conferences. He was a recipient of the Best Paper Award at the IEEE Vehicular Technology Conference in 2013, the IEEE International Conference on Communications in 2014, and a recipient of the prestigious Royal Academy of Engineering Research Fellowship (2015–2020).

Maged Elkashlan (M’06) received the Ph.D. degree in electrical engineering from the University of British Columbia, in 2006. From 2007 to 2011, he was with the Wireless and Networking Technologies Laboratory, Commonwealth Scientific and Industrial Research Organization, Australia. He held an adjunct appointment with the University of Technology Sydney, Australia. In 2011, he joined the School of Electronic Engineering and Computer Science, Queen Mary University of London, U.K., as an Assistant Professor. He also holds visiting faculty appointments with the University of New South Wales, Australia, and the Beijing University of Posts and Telecommunications, China. His research interests include massive MIMO, millimeter wave communications, and heterogeneous networks.

Dr. Elkashlan was a recipient of the Best Paper Award at the IEEE International Conference on Communications in 2014 and 2016, the IEEE International Conference on Communications and Networking in China in 2014, and the IEEE Vehicular Technology Conference in 2013. He currently serves as an Editor of the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS, the IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY, and the IEEE COMMUNICATIONS LETTERS.

George K. Karagiannidis (M’96–SM’03–F’14) was born in Pithagorion, Greece. He received the University Diploma (five years) and Ph.D. degrees in electrical and computer engineering from the University of Patras, in 1987 and 1999, respectively. From 2000 to 2004, he was a Senior Researcher with the Institute for Space Applications and Remote Sensing, National Observatory of Athens, Greece. In 2004, he joined the faculty of the Aristotle University of Thessaloniki, Greece, where he is currently a Professor with the Electrical and Computer Engineering Department, and the Director of the Digital Telecommunications Systems and Networks Laboratory. He is also a Honorary Professor with South West Jiaotong University, Chengdu, China.

Dr. Karagiannidis has authored or co-authored over 400 technical papers published in scientific journals and presented at international conferences. He has also authored the Greek edition of a book entitled Telecommunications Systems and co-authored the book entitled Advanced Optical Wireless Communications Systems (Cambridge, 2012). His research interests are in the broad area of digital communications systems with emphasis on wireless communications, optical wireless communications, wireless power transfer and applications, molecular communications, communications and robotics, and wireless security. He was a recipient of the 2015 Thomson Reuters Highly Cited Researcher Award. He has been involved as the General Chair, the Technical Program Chair, and a member of Technical Program Committees in several IEEE and non-IEEE conferences. He was an Editor of the IEEE TRANSACTIONS ON COMMUNICATIONS and the EURASIP Journal of Wireless Communications and Networks, a Senior Editor of the IEEE COMMUNICATIONS LETTERS, and several times Guest Editor of the IEEE JOURNAL ON SELECTED AREAS IN COMMUNICATIONS. From 2012 to 2015, he was the Editor-in-Chief of the IEEE COMMUNICATIONS LETTERS.
Arumugam Nallanathan (S’97–M’00–SM’05) is a Professor of Wireless Communications with the
Department of Informatics, King’s College London (University of London). He served as the Head
of Graduate Studies with the School of Natural and Mathematical Sciences, King’s College London,
from 2011 to 2012. He was an Assistant Professor with the Department of Electrical and Computer
Engineering, National University of Singapore, from 2000 to 2007. His research interests include 5G wire-
less networks, molecular communications, energy harvesting, and cognitive radio networks. He published nearly 300 techni-
cal papers in scientific journals and international conferences. He was a co-recipient of the Best Paper Award presented at the IEEE International
Conference on Communications 2016 (ICC) and the IEEE International
Conference on Ultra-Wideband 2007 (ICUWB). He is an IEEE Distinguished
Lecturer.
He is an Editor of the IEEE TRANSACTIONS ON COMMUNICATIONS
and the IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY. He was an Editor of the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS
from 2006 to 2011, the IEEE WIRELESS COMMUNICATIONS LETTERS,
and the IEEE SIGNAL PROCESSING LETTERS. He served as the Chair for
the Signal Processing and Communication Electronics Technical Committee
of the IEEE Communications Society, the Technical Program Co-Chair
(MAC track) for the IEEE WCNC 2014 and the IEEE International
Conference on UWB 2011, the Co-Chair for the IEEE GLOBECOM 2008
(Signal Processing for Communications Symposium), the IEEE ICC 2009
(Wireless Communications Symposium), the IEEE GLOBECOM 2011 (Signal
Processing for Communications Symposium), the IEEE ICC 2012 (Signal
Processing for Communications Symposium), and the IEEE GLOBECOM
2013 (Communications Theory Symposium), and the General Track Chair for
the IEEE VTC 2008. He was a recipient of the IEEE Communications Society
SPCE Outstanding Service Award in 2012 and the IEEE Communications
Society RCC Outstanding Service Award in 2014.
