Abstract

Generic generalisations (e.g. ‘tigers have stripes’, ‘ducks lay eggs’) refer to a characteristic property of a kind. Recently, the generics-as-default view has posited that we have a bias towards interpreting universally quantified statements as generic. Evidence offered for this view is the Generic Overgeneralisation (GOG) effect, which refers to the documented tendency of participants to misinterpret a quantificational statement like ‘all ducks lay eggs’ as if it were a generic and thus accept it as true, even though they know it is false. Across two experiments in English and Greek we systematically addressed the relevance of context and quantifier domain restriction for this kind of behaviour. Participants judged generic majority characteristic statements like ‘tigers have stripes’ or statements with universal quantifiers with different sensitivity to quantifier domain restriction preceded by one of three levels of context (neutral, contradictory and supportive). We found that context significantly affected the rates at which participants accepted universally quantified statements. Our results demonstrate that quantifier domain restriction is a viable alternative explanation for a significant proportion of the judgements of universally quantified statements that have been called GOG errors.

Keywords: context; generalisation; generics-as-default; genericity; quantification; quantifier domain restriction

1. Introduction

Quantificational generalisations, as in (1)-(2), are expressed in quantitative, statistical terms, while generic generalisations, as in (3)-(4), make general claims about kinds of entities and refer to a property that is characteristic of the kind in question, but not necessarily statistically prevalent, as in (4):

- (1) Some lions live in cages.
- (2) All lions eat meat.
- (3) Lions roar.
- (4) Lions have manes.

Generic generalisations have long been studied in formal semantics, within which genericity is frequently viewed as a species of quantification involving a covert sentential operator called ‘GEN’ (Krifka, Pelletier, Carlson, ter Meulen, Chierchia & Link, 1995). However, how to characterise their semantic interpretation and how to model their truth conditions remain controversial topics (see Dahl, 1975; Carlson, 1977; and more recent discussion in Mari, Beyssade, & del Prete, 2013).

In recent years, a growing body of experimental and developmental psychological work on the topic proposes that genericity is categorically different from (and significantly simpler than) quantification (Leslie, 2007, 2008; Gelman, 2010). This latter hypothesis, called the *generics-as-default* view, treats generics as a cognitive default and argues that they have priority both in terms of ontogeny (children understand and produce generics before quantified statements; see e.g. Hollander, Gelman & Star, 2002; Gelman, 2010) and in terms of cognitive complexity (quantified statements are misunderstood or misrecalled more often than generics in experimental tasks, see e.g. Leslie, Khemlani, & Glucksberg, 2011; Leslie & Gelman, 2012). This view posits a ‘generic bias’, which is founded on a dual view of cognition that assumes a distinction between fast, automatic and effortless System 1 and slow, effortful, higher-level and rule-governed System 2 (Kahneman & Frederick, 2002). One piece of evidence for the existence of two systems is the fact that they can lead to conflicting judgments. Leslie (2007:395) cites Frederick’s (2005) “cognitive reflection test”, to illustrate the two systems: “A bat and a ball cost \$1.10 in total. The bat costs \$1 more than the ball. How much does the ball cost?” Most people report an initial inclination to answer “10 cents”. System 1 supplies this first fast, but erroneous response. The correct response of “5 cents”

1
2
3 requires algebraic reasoning, part of the slower System 2. Leslie (2007:397) proposes that
4 generics are part of System 1 and quantifiers part of System 2:
5
6
7

8 The evidence surveyed so far suggests that System 1 - the more primitive system - is
9 not particularly sensitive to information about how much or how many. I suggest that
10 generics are judgments issued by System 1. They are thus non-quantificational; they do
11 not depend on considerations of quantity, or any such information easily captured by
12 set-theory. They are, however, automatic, effortless, and cognitively basic. Quantifiers,
13 in contrast, express judgments issued by System 2, the rule-governed, extension-
14 sensitive, higher-level system. Quantifiers do depend on considerations such as how
15 much and how many. They are thus easily describable in the terms of set-theory.
16
17
18
19
20
21
22
23

24 Inspired by other cases of System 1 overuse like the one mentioned above (Frederick, 2005),
25 Leslie (2007) anticipates similar errors in the interpretation of generic (System 1) and
26 quantificational (System 2) statements, which would take the shape of a ‘generic bias’.
27 According to the generics-as-default proponents, evidence for the suggested ‘generic bias’
28 could come from different sources. Two main examples of overuse of System 1 that leads to
29 overgeneralisation of quantifiers as generics have been described in the literature: (a) 3-year-
30 old children treat quantified statements with ‘some’ and ‘all’ as if they were generic more
31 often than the reverse (Hollander et al., 2002) and (b) adults misunderstand universal
32 quantificational statements as generics and show a tendency to endorse false universal
33 generalisations when the corresponding generic is true (e.g. they accept ‘all ducks lay eggs’
34 as true despite knowing that male ducks do not do so; Leslie et al., 2011). This led Leslie et
35 al. (2011) to proclaim the Generic OverGeneralisation effect (‘GOG’ henceforth) as one of
36 the main pieces of evidence in support of the generics-as-default view. The GOG effect is
37 defined as “the tendency to overgeneralise from the truth of a generic to the truth of the
38 corresponding universal statement” (Leslie et al. 2011, p. 17). This tendency is attributed to
39 generics’ default nature (see Prasada, Khemlani, Leslie, & Glucksberg, 2013, for more
40 discussion of this conceptually based approach to generics).
41
42
43
44
45
46
47
48
49
50
51
52

53 Furthermore, according to this view, the fact that no language has a dedicated overt
54 ‘GEN’ operator (Dahl, 1995) does not come as a surprise: given that generics are the most
55 primitive default generalisations, children do not need to learn anything special in order to
56 acquire them. Generics come essentially for free. In contrast, effortful, non-default
57 quantificational generalisations require overt linguistic expression. However, while assigning
58
59
60

1
2
3 generics to a more basic, unmarked System 1, mode of thinking may sound intuitive at some
4 level, it rests on a vague and undefined notion of markedness. Leslie (2008) cites a pattern
5 discussed in Chomsky (2000), but she never spells out precisely what formalisation of
6 markedness she relies on. Intuitively, it seems that what is at stake is surface level overt
7 realisation (the third notion of markedness in Haspelmath, 2006).
8
9

10
11
12 In previous work (Lazaridou-Chatzigoga, Stockall, & Katsos, 2017) we considered
13 the conceptual arguments for the generics-as-default hypothesis and the status of the GOG
14 effect as a processing error. We concluded that evidence that the GOG responses are
15 erroneous judgments is less compelling than it might at first appear.
16
17

18
19 The goal of this paper is to provide empirical evidence that the pragmatic
20 phenomenon of quantifier domain restriction (QDR henceforth) is an alternative viable
21 explanation for a substantial part of the attested behaviour, that is, of the fact that adults
22 accept statements like ‘all tigers have stripes’ and ‘all ducks lay eggs’ as true. Our rationale
23 is that in order to evaluate the theoretical and psychological validity of a new mechanism for
24 the interpretation of quantified statements, such as the GOG effect, one needs to carefully test
25 and consider the already available alternative explanations, which rely on independently
26 established factors. We will show that context affects the rates at which participants accept
27 universally quantified statements as true in a way that relies on QDR and on the differing
28 sensitivity different universal quantifiers show to it. Our results show that the attested
29 behaviour can be largely explained by QDR, a phenomenon about which we have abundant
30 independent evidence. The size of the QDR effect in our experiments shows that it is a major
31 contributing factor to the attested behaviour. If there is a GOG effect then, as argued in much
32 recent literature, it is smaller than was originally proposed. However, QDR does not explain
33 all of the *prima facie* ‘mistaken’ acceptances of universal statements and therefore there is
34 still some residual behaviour to be accounted for, so we also make a broader point: In order
35 to properly evaluate the contribution of the GOG effect, we need to engage in quantitative
36 linguistically-informed research that takes into account all the other known factors that lead
37 to GOG-like behaviour, since QDR is only one of them.

51 We ran the same experiment in English and Greek and confirmed that our context
52 manipulation worked in two different languages. By doing so, we also addressed the
53 unmarkedness claim for generics, as the generic statements mostly studied thus far were bare
54 plural generics in English, which lend themselves easily to the idea of unmarkedness, as they
55 are characterised by the absence of a determiner. In Greek, definite plurals are used instead of
56 bare plurals making generics look less ‘unmarked’ and, moreover, the configuration of
57
58
59
60

1
2
3 nominals involved in genericity, quantification and definiteness differs from English. Our
4 results point further to the significance of doing experimental work on genericity and
5 quantification cross-linguistically.

10 2. The GOG effect: background and alternative explanations 11 12

13 The generics-as-default view argues that people have the tendency to interpret quantified
14 statements as if they were generic, e.g. evaluating a statement quantified with ‘all’ or ‘some’
15 as though it were a generic. Support for this view is based on data from universal and
16 existential statements from English, Mandarin and Quechua-speaking children (see e.g.
17 Hollander et al., 2002; Tardif, Gelman, Fu, & Zhu, 2012; Mannheim, Gelman, Escalante,
18 Huayhua, & Puma, 2011 for each language respectively)² and on data from universal
19 statements from English-speaking adults, under certain circumstances (see Khemlani, Leslie,
20 Glucksberg, & Rubio-Fernandez, 2007; Leslie et al., 2011; Meyer, Gelman, & Stilwell,
21 2011).
22
23
24
25
26
27
28

29 The first detailed investigation of the scope of the GOG effect in adults is found in
30 Leslie et al. (2011). In their experiment 1, participants performed a truth-value judgement
31 task on sentences that were presented in generic, universal (‘all’), or existential (‘some’)
32 form. The statements involved different kinds of properties: quasi-definitional (‘triangles
33 have three sides’), majority characteristic (‘tigers have stripes’), minority characteristic
34 (‘ducks lay eggs’), majority non-characteristic (‘cars have radios’), striking (‘pit bulls maul
35 children’), and false generalisations (‘Canadians are right-handed’). Leslie et al. report that
36 adults sometimes judged universal statements as true, despite knowing that they were truth-
37 conditionally false. For example, participants judged a statement like ‘all tigers have stripes’
38 as true, even though it is false given that there are albino tigers, and they accepted ‘all ducks
39 lay eggs’, even though only sexually mature female ducks have this capacity. Leslie et al.
40 claim that the participants made this ‘error’ because they relied on the corresponding generic
41 statements, which are true (‘tigers have stripes’, ‘ducks lay eggs’). The authors find that the
42 GOG effect is restricted to *characteristic* properties and that it occurs in more than half the
43 trials: 78% for majority characteristic and 51% for minority characteristic statements.
44
45
46
47
48
49
50
51
52
53
54

55 Leslie et al. entertained three alternative explanations, which they argue are ruled out
56 with subsequent experiments: a) ignorance of the relevant facts, b) subkind interpretation,
57
58
59

60 ² See Lazaridou-Chatzigoga, Katsos, & Stockall (2015) for a critical review of the child language evidence.

1
2
3 and c) QDR. Thus, Leslie et al. (2011) claimed to have evidence for a generic bias, according
4 to which people sometimes treat universally quantified statements as if they were generic.
5
6
7

8 In previous work (Lazaridou-Chatzigoga, Stockall, & Katsos, 2017) we provided conceptual
9 arguments against the rejection of the above alternative explanations, and also considered a
10 fourth explanation, the atypical behaviour of ‘all’. Here is a summary (alongside our
11 criticism):
12
13
14

- 15 a. *ignorance of the relevant facts*: participants might simply be ignorant of the relevant
16 facts that mainly involve primary or secondary sexual characteristics relevant to
17 mating and reproduction. For instance, for ‘all ducks lay eggs’ participants might not
18 know that male ducks do not lay eggs. Leslie et al. addressed this through a
19 knowledge task (experiments 3a,b) and they were able to confirm that participants
20 knew the facts. Interestingly, though, acceptance of statements like ‘all ducks lay
21 eggs’ fell to 33% when the knowledge task was performed before judging the critical
22 statements (compared with 51% in the original experiment). While Leslie et al. are
23 correct to point out that these statements were still accepted as true at a higher rate
24 than they ought to be, we take an 18% reduction as indicative that alternatives to the
25 GOG explanation are worth pursuing.³
26
27
28
29
30
31
32
33
34 b. *subkind (taxonomic) interpretation*: participants might be interpreting ‘all ducks lay
35 eggs’ as ‘all kinds/types of ducks lay eggs’, including the Mallard, the Eider, the
36 Goldeneye, etc. Under such a subkind interpretation, the correct response is to accept
37 them, thus there is no need to look for explanations of that behaviour. Leslie et al.
38 rejected this explanation based on their experiment 2b, where participants were asked
39 to provide a paraphrase of each statement trying to keep the paraphrase as close to the
40 meaning of the original statement as possible. Participants used subtyping language in
41 only 1% in their paraphrasing. The fact, though, that participants were not *conscious*
42 of the fact that they might have interpreted the statement as involving subkinds is
43 non-conclusive, as the distinction between implicit knowledge and explicit knowledge
44 is a fundamental one in cognitive science. For instance, Dienes & Perner (2002)
45 discuss various cases of participants employing rules in categorisation and judgment
46 tasks, which they are unable to make explicit when asked. Further research actually
47
48
49
50
51
52
53
54
55
56
57
58

59 ³ For some puzzling effects related to statements like ‘tigers have stripes’ when participants did the knowledge
60 task before evaluating the statements, see our discussion Lazaridou-Chatzigoga, Stockall, & Katsos (2017).

manipulating the availability of a subkind interpretation is required before rejecting this explanation.

- c. *quantifier domain restriction*: participants might be interpreting a statement like ‘all ducks lay eggs’ as applying only to a relevant subset of ducks, namely the mature fertile female ducks. This is based on the assumption that quantified statements are interpreted within a context, which may restrict the scope of the quantifier (as per Stanley & Szabó, 2000; Stanley, 2002). This alternative explanation was addressed in Leslie et al.’s experiment 2a, where they provided the participants with a context which supplied population information (e.g. “Suppose the following is true: there are 431 million ducks in the world. Do you agree with the following: all ducks lay eggs”). The GOG effect dropped by 18% for majority characteristic and by 21% for minority characteristic statements with respect to their experiment 1, but it still occurred on a substantial portion of trials for statements with ‘all’ (60% for majority and 30% for minority characteristic). QDR was also investigated through their experiment 2b, which included a paraphrase task. Of the paraphrases provided by the participants only 1.6% included a subset interpretation (e.g. “female ducks lay eggs”). The same criticism outlined in (b) above applies here with respect to the distinction between implicit and explicit knowledge. Thus, Leslie et al. discarded QDR as a major alternative explanation for the GOG effect. For more discussion of QDR see section 2.1 below.
- d. although not an explanation considered by Leslie et al. (2011), a fourth explanation could be the *atypical behaviour of ‘all’*: ‘all’ cannot be treated as a representative universal quantifier. It has been argued that a) ‘all’ participates in fallacious reasoning (Jönsson & Hampton, 2006), b) ‘all’ is prone to hyperbolic/loose use with a meaning similar to ‘very many’ or ‘almost all’ (see Claridge, 2011, for work on corpus linguistics), c) ‘all’ is ambiguous between distributive and collective interpretation (Beghelli & Stowell, 1997)⁴. Thus, we argue that other universal quantifiers in English and other languages can offer a better test of the generics-as-default hypothesis.

⁴ A further potential licenser of a ‘true’ response is the possibility of an association between the concept TIGER and the concept STRIPE, that is, ‘all tigers have stripes’ might be judged as true, because the concept TIGER is strongly associated with the concept STRIPE. For instance, in a structural model of semantic memory (Collins and Quillian, 1969) the concept TIGER would be linked to the concept STRIPE or in a model based on semantic features the feature STRIPE would be part of the meaning of the word TIGER (Smith, Shoben, and Rips, 1974). See Hampton (2015) for further details on these models as well as discussion of their shortcomings.

1
2
3 In sum, Leslie et al.'s (2011) dismissal of the above explanations is not as convincing as they
4 argue. We proposed that ignorance, subkind interpretation, atypical behaviour of 'all' and
5 QDR might all play a role in explaining the attested behaviour by adults (ignorance and QDR
6 were responsible for a 18/21% reduction in 'true' responses respectively and subkind
7 interpretation and QDR were found in paraphrases at 1/1.6% rates respectively in Leslie et
8 al.'s own experiments). If the effects of each of these factors are independent and cumulative,
9 the residue of real errors in Leslie et al. (2011)'s experiment 1 left to explain as GOG is 40%
10 or less out of the 78% for majority characteristic statements, and as low as about 10% out of
11 the 51% for the minority characteristic statements. We also argued that even the name of the
12 GOG effect might be misleading. The effect mainly tries to capture the behaviour observed
13 with 'all' only when the property in question is characteristic, which supposedly receives a
14 generic interpretation as a result of an overgeneralisation bias. Thus, perhaps a better name
15 for that effect would be 'Quantifier Reinterpretation' effect, because this term would direct
16 the focus where we believe it belongs: on the interpretation of 'all', or more generally of
17 quantifiers, rather than the interpretation of generic statements.
18
19
20
21
22
23
24
25
26
27

29 In this paper, we look for empirical evidence to test these conceptual arguments,
30 focusing on QDR and its relevance for the attested behaviour.
31
32
33

34 3. Interpreting universally quantified generalisations 35 36 37

38 3.1 The behaviour attributed to the GOG effect within the generics-as-default view 39 40

41 As mentioned above, Leslie et al. (2011) addressed QDR as an alternative explanation for
42 why participants accept statements like 'all tigers have stripes' or 'all ducks lay eggs'. The
43 contexts used by Leslie et al. (2011) relied on population information (e.g. "Suppose the
44 following is true: there are 431 million ducks in the world. Do you agree with the following:
45 all ducks lay eggs?"). This information was supposed to prime quantification over every
46 individual duck in the world, and thereby to make it difficult/impossible to interpret 'all' as
47 restricted to only the ducks that are presupposed by 'lay eggs'. If acceptance of 'all ducks lay
48 eggs' without any context was driven by QDR, Leslie et al. predicted that it would disappear
49 in the context of population information. These contexts though only had a moderate effect
50 on participant behaviour. While the GOG effect dropped with respect to the rates they
51 obtained in an experiment without any context, there was still a high acceptance of such
52 statements.
53
54
55
56
57
58
59
60

1
2
3 Leslie et al. (2011) argue that “the effect cannot be entirely explained this way [i.e. via
4 QDR], since the effect remained in a context that encouraged generalization across each and
5 every individual in the world”. While they only find the effect with characteristic statements
6 and with the universal quantifier ‘all’, they often discuss their results as if they applied to all
7 universal statements (e.g. in Leslie et al. 2011, p. 18: “the generics-as-default hypothesis
8 predicts that adults will tend to incorrectly endorse false universal statements if the
9 corresponding generic is true”; “the tendency to substitute a judgment of the generic for the
10 universal will be generally more successful when the property in question is a characteristic
11 one”).

12
13
14
15
16
17
18
19 Leslie et al. (2011) thus discarded QDR as a contributing factor to the attested behaviour.
20 On the basis of the additional experiments they conducted to address alternative explanations,
21 they concluded that this behaviour can only plausibly be explained if we attribute it to
22 Leslie’s (2008) and Gelman’s (2010) hypothesis that generics express primitive, default
23 generalisations. Thus, it is generics’ default nature that leads participants to misinterpret
24 universally quantified statements as if they were generic. Treating this behaviour as an error
25 is an integral part of this approach, as this lends support to the existence of a strong generic
26 bias that is expected given that generics involve more basic (System 1) generalisations, while
27 universally quantified generalisations concern non-default, more effortful ones.

28
29
30
31
32
33
34 If one were to design a study addressing the relevance of context via manipulating
35 different levels of it, on our understanding of the generics-as-default view, proponents of that
36 view would expect that different kinds of context should give rise to similar levels of GOG
37 responses, for all universal quantifiers. The ‘more marked’ system 2 quantified statements
38 should be ‘erroneously’ interpreted as generic statements at similar rates to previous
39 experiments. Proponents of the generics-as-default view would expect only very moderate
40 differences between different kinds of context, or between different quantifiers, since the
41 generics-as-default view is that participants fail to interpret the quantifiers as universal
42 quantifiers, and that they erroneously accept the generic statement counterparts instead. In
43 sum, the generics-as-default view proposes that the attested behaviour is due to an underlying
44 generic bias that manifests as a failure to correctly process the quantifier and not to any
45 specific properties of the quantifier itself. Thus, in principle it should make no difference
46 what the quantifier is, and this view is silent about how to explain any potential differences
47 one might observe between different universal quantifiers as a function of context.

3.2 Quantifier domain restriction as an alternative explanation

We argue that QDR needs to be investigated as a viable alternative explanation for much of the data attributed to the GOG effect, building on a design used by Lazaridou-Chatzigoga & Stockall (2013). We focus on QDR among the other alternative explanations given that it is a pervasive phenomenon affecting quantifiers and their interpretation within a context, and is routinely invoked in quantification (von Stechow, 1994). According to QDR, the domain of a quantifier can be restricted: in a discourse like *'There was rhubarb pie for dessert. Everyone developed a rash'* (example modified from von Stechow, 1994, p. 33), 'everyone' does not quantify over all the individuals in the world, but rather over the contextually restricted set of individuals who ate the rhubarb pie. Furthermore, listeners are known to be charitable (Grice, 1975). Thus, in a conversation one assumes that speakers take the most sensible positions and make the most plausible assertions. Under this view, interpreting 'everyone' as quantifying over all the individuals in the world seems a rather unlikely intended interpretation and moreover one that is not charitable to the speaker because it renders her utterance false, whereas interpreting 'everyone' with respect to the available set of individuals is not only plausible but also charitable to the speaker. How we encode QDR in the grammar is currently under debate and opinions vary as to whether QDR is part of the syntax/semantics (Stanley & Szabó, 2000; Stanley, 2002, von Stechow, 1994; Martí, 2003; Giannakidou, 2004), or of the pragmatics (see e.g. Recanati, 1996) - this is not the place to decide upon this issue (see Kratzer, 2004). Irrespective of whether one represents QDR as a syntactic, semantic or pragmatic phenomenon, there is an abundance of independent motivation for its existence.

To come back to the statements relevant for our studies, if QDR was relevant when participants interpreted statements like 'all ducks lay eggs' or 'all tigers have stripes' it would mean that participants would interpret these statements as applying only to a relevant subset of the kind, that is, the mature fertile female ducks in the case of 'all ducks lay eggs' and the normal tigers in the case of 'all tigers have stripes'. If participants are indeed restricting the domain to these relevant sets, then their behaviour is not erroneous, as they are indeed expected to accept these statements under a QDR interpretation.

We hypothesised that if we could show that the rate at which participants 'erroneously' accept universally quantified statements (the behaviour labelled the GOG effect) can be altered by carefully manipulating different levels of contextual information preceding the critical utterance, we would have evidence that the observed tendency to accept universally quantified statements as true can be largely explained through QDR, an

1
2
3 independently motivated mechanism, and that resorting to an explanation such as the GOG
4 would be less appealing.
5

6 The contexts used by Leslie et al. (2011) relied on population information (e.g.
7 “Suppose the following is true: there are 431 million ducks in the world. Do you agree with
8 the following: all ducks lay eggs”) and only had a moderate effect on participant behaviour.
9 We argue that these contexts did not succeed in making salient the potential restricted domain
10 against which participants might be interpreting the statements, that is, they did not make the
11 set of female ducks salient. Instead, they provided participants with an estimate about the
12 total number of ducks in the world. Our contexts would crucially include information that
13 explicitly related to the potential restricted domains. We provide an overview of our studies
14 in the next section.
15
16
17
18
19
20
21
22
23

24 4. Overview of the studies

25
26
27 In the present studies we investigated QDR as a viable alternative explanation for much of
28 the data attributed to the GOG effect, building on a design used by Lazaridou-Chatzigoga &
29 Stockall (2013). Because of the design we adopted, we focused only on majority
30 characteristic statements (‘tigers have stripes’) leaving minority characteristic statements
31 (‘ducks lay eggs’) for future investigation. The majority characteristic items evoked a much
32 larger ‘GOG’ effect in the original study, and they moreover constitute the more general case.
33 Minority characteristic statements seem to exclusively involve primary or secondary sexual
34 characteristics of animal kinds. Likely due to this restriction, of the twelve minority
35 characteristic items in the original study by Leslie et al. (2011), the same predicate was
36 repeated either two (‘deer have antlers’, ‘moose have antlers’) or three times (‘ducks lay
37 eggs’, ‘insects lay eggs’, ‘snakes lay eggs’). Therefore, if we excluded second and third
38 occurrences of a predicate as well as one item that was removed post-hoc from their analyses
39 (‘cardinals are red’), we would have been left with only 8 items in our item-base. Our own
40 attempts to construct additional, non-repeated items proved difficult because of the need to
41 resort to more specialised vocabulary such as ‘udders’ or ‘foals’, or to rely on knowledge
42 unlikely to be broadly shared⁵. Thus, we decided to leave minority characteristic items out of
43 this study.

In our design, we manipulated context and investigated the relevance of QDR for the attested behaviour. We reasoned that when people accept a statement like ‘all tigers have stripes’ they interpret it as a claim only about the relevant restricted set of normal instances of the kind, which are characterised by having stripes, as the counterexamples may not be spontaneously accessible. We decided to use three levels of contexts and varied the context preceding the critical utterance as follows: a) neutral, where the information in the context does not interact with the truth value of the critical statement, b) contradictory, where exceptions which should rule out a universally quantified statement are made salient, and c) supportive, where the generality of the critical property is made salient through a paraphrase. Examples of each context level are given below:

- (5) a. **neutral**: Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose playful games visitors love to watch and photograph.
 b. **contradictory**: Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose fur is all white due to a recessive gene that controls coat colour.
 c. **supportive**: Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose black and orange coats visitors love to photograph.

The contradictory and supportive contexts would make the relevant domain for QDR salient, while the neutral context would serve as a baseline measure. The contradictory and supportive contexts turned the implicit restriction to ‘all normal’ individuals into an explicit one by either highlighting some abnormal individuals (contradictory) or by using a paraphrase that suggested that the relevant individuals had the relevant property, i.e. they were normal individuals (supportive).

As for generics, standardly they are argued to resemble adverbial quantification and to differ from nominal quantifiers in that they resist contextual narrowing to a salient set of entities. The following examples (Krifka, 1987, p.7) show that while the nominal argument of ‘every’ (‘lion’ in (6)), is subject to QDR and can refer to the set of lions introduced in the context, this is not a possible interpretation for the indefinite singular ‘a lion’ in (6), which expresses a property of lions in general. Thus, the truth conditions of generics seem to remain stable across different contexts, while the truth conditions of quantified statements vary depending on the context of utterance.

- (6) a. (Out of the blue): Every lion has a mane. (non-restricted)

- 1
2
3 b. There are lions and tigers in the cage. Every lion has a mane.
4 (restricted or non-restricted)
5
6 c. There are lions and tigers in the cage. A lion has a mane.
7 (non-restricted only)
8
9
10 d. There are lions and tigers in the cage. A lion always has a mane.
11 (non-restricted only)
12
13
14

15 Following the standard view of generics that considers them to be immune to context and
16 given that the generic statements were chosen to be ‘true’, participants were expected to
17 accept generics as true at equally high rates in all contexts – even in the contradictory context
18 given generics’ tolerance of exceptions. Intuitively though, the saliency of the exceptions
19 might give rise to lower acceptance rates in the contradictory context compared to the other
20 conditions, a result that would align with other proposals in the literature that, contrary to the
21 standard view, posit context sensitivity for generics (Pelletier and Asher, 1997; Cohen 2001;
22 Nickel, 2008; see Sterken, 2015 for an overview). This sensitivity is based on examples like
23 ‘dobermans have floppy ears’, which is true in the context of evolutionary biology, but false
24 in the context of dog breeding (Nickel, 2008). According to these views we might expect
25 some context sensitivity even for generics.
26
27

28 Note though that the contrast in (6) does not obtain for all universal quantifiers
29 equally. Universal quantifiers are not equally subject to QDR in all contexts. ‘All’, ‘all the’,
30 ‘every’ and ‘each’ are all universal quantifiers, but they differ in terms of distributivity
31 (Vendler, 1962; Gil, 1995), and on whether they allow, may resist or require QDR. Using
32 different types of universal quantifiers is essential to test the scope of a QDR-based
33 explanation of the GOG effect, as universal quantifiers show different sensitivity to QDR:
34 QDR is less likely if the universal quantifier does not require/may resist linking with a set
35 under discussion (Partee, 1995; Matthewson, 2001), as is the case with ‘all’, compared to ‘all
36 the’ and ‘each’, which have to be interpreted as D(iscourse)-linked (Pesetsky, 1987). There
37 seems to be essentially an ordering of preference with respect to QDR: ‘all the’ and ‘each’
38 require it, while ‘all’ allows or may resist it, as the following examples illustrate:
39
40
41
42
43
44
45

47
48
49
50
51
52
53

- 54
55 (7) Context: There are three cats in the garden, which happen to be black.
56 a. All cats are black.
57 b. All the cats are black.
58 c. Each cat is black.
59
60

1
2
3
4
5 In the above context, (a) would most probably be assigned a non-restricted interpretation and
6 would be treated as false. It is possible though for (a) to be treated as true, if one interprets (a)
7 as referring to ‘all cats in the garden’. According to Matthewson (2011), ‘all’ is not
8 susceptible to QDR and such an interpretation is expected to be infelicitous. We believe
9 though that this is an empirical question that needs to be tested. In the above context, both (b)
10 and (c) should be treated as true, given that ‘all the’ and ‘each’ necessarily have to be
11 interpreted with respect to the context of utterance, which happens in this case to render them
12 true.
13
14
15
16
17
18

19 These differences among universal quantifiers motivate the use of several of them in an
20 experiment addressing QDR. Using different universal quantifiers would also address the
21 possibility that the atypical nature of ‘all’ plays a part in generating the attested GOG
22 behaviour.⁶ Thus, in addition to manipulating context, a compelling test of the QDR view
23 also requires testing whether the GOG effect is observed only with ‘all’. As we discussed
24 above, there are reasons to believe that ‘all’ is not a representative universal quantifier. Only
25 Lazaridou-Chatzigoga & Stockall (2013) have tested universal generalisations other than
26 ‘all’, obtaining differences between ‘all’, ‘every’ and ‘all the’ that supported further
27 investigation of different types of universal quantification.
28
29
30
31
32
33

34 In the neutral condition, the predictions of the QDR account critically diverge from the
35 generics-as-default view, as we expect that participants’ responses are not biased towards a
36 generic interpretation, but are rather dependent on the sensitivity of the quantifier to QDR
37 and on the available non-QDR alternatives to accepting these statements. The neutral context
38 makes some individuals of a kind salient, i.e. a set of tigers, without providing any
39 information relevant to the property in question. The neutral context will provide a baseline
40 measure in order to observe any differences between quantifier types, while keeping the
41 information supplied by QDR constant. To judge whether ‘all the’ or ‘each’ statements are
42 true in the neutral context, participants are required to access their own knowledge about the
43 kind under discussion. We predict mostly ‘true’ responses, that is, that participants will
44 accept the statements, given that the context does not provide any reason to doubt that the
45

50
51
52
53

54
55
56
57
58
59
60
⁶ It would be also worth testing whether it is only D-quantifiers (that is, Determiner-quantifiers like ‘all’ and ‘every’), that show this behaviour or whether A-quantifiers (that is, Adverbs, Auxiliaries, Affixes, etc. like ‘always’, ‘usually’, ‘must’ etc.) would be also affected. In principle, if the attested behaviour is due to a cognitive bias, we should expect to find it with all kinds of quantifiers. The relevance of QDR as a major alternative explanation for the attested behaviour could be tested more broadly if quantificational adverbs like ‘always’, ‘usually’ and ‘typically’ were tested as well. We leave that investigation for future research.

1
2
3 normal situation holds. Participants should rely on their previous experience of the world in
4 order to give a judgment. Statements with ‘all’ in the neutral context could evoke acceptance
5 of the statement for any of the reasons discussed above (ignorance, subkind interpretation,
6 loose/hyperbolic interpretation). The availability of a wider range of possible interpretations
7 for ‘all’ might give rise to higher acceptances compared to ‘all the’ and ‘each’.
8
9

10
11 In the contradictory and supportive contexts, the QDR view predicts variation in
12 acceptances: across the board, the contradictory context should decrease acceptance rates and
13 the supportive context should increase them. In the contradictory context, the QDR view
14 predicts low acceptance rates for ‘all the’ and ‘each’ statements, as participants are required
15 to interpret the quantifiers as referring for instance to the stripeless tigers just introduced in
16 the context. On the other hand, given that ‘all’ may resist a restricted interpretation,
17 participants are not expected to adopt a QDR interpretation. Thus, ‘all’ statements could still
18 trigger relatively high acceptances, as participants could still alternatively generate any of the
19 other options (namely, the subkind interpretation or a hyperbolic/loose interpretation), which
20 would license acceptance of the statement. They could not, however, be ignorant of the
21 existence of stripeless tigers, so we would still predict that acceptances for ‘all’ would be
22 lower in the contradictory context than in the neutral or supportive contexts.
23
24
25
26
27
28
29
30
31

32 In the supportive context, the QDR view predicts that, given that the QDR
33 interpretation is easily available, and charitable, and because the non-QDR alternatives also
34 license a ‘true’ response (subkind interpretation, loose/hyperbolic interpretation), acceptance
35 rates for ‘all’ in the supportive context should be higher than in the neutral context. For ‘all
36 the’ and ‘each’, explicitly predicating variegated coloration of the tigers under discussion
37 means that the only licit judgement to the statements would be ‘true’, thus acceptances are
38 expected to be higher than in the neutral context.
39
40
41
42
43
44
45

46 In our studies, we addressed generics cross-linguistically by running the same study in two
47 languages, English and Greek. This enabled us to see whether the context manipulation in our
48 design would work in a language different from English and furthermore addressed the
49 following two issues: (a) the unmarkedness claim with respect to generics, and (b) the fact
50 that Greek has a different repertoire of articles and quantifiers, i.e., the configuration of
51 nominals involved in genericity, quantification and definiteness differs from English
52 (Chierchia, 1998; Longobardi, 2001).
53
54
55
56
57

58 Early articulations of the generics-as-default hypothesis (Leslie 2007, 2008) appeal to a
59 notion of markedness they attribute to Chomsky (2000). Leslie (2008, p. 24) discusses
60

1
2
3 Chomsky's example of 'John climbed the mountain' adopting the suggestion that "this is
4 understood as meaning that John climbed *up* the mountain; to obtain the interpretation that
5 John climbed *down* the mountain, we must explicitly use the preposition 'down'. The
6 unmarked case 'climbed the mountain' is never interpreted as *climbed down the mountain*."
7
8 The proposal is that we conceive of *climbing* as *climbing up* in the default, unmarked case,
9 and have to use a more marked form to express the opposite.

10
11
12
13 Leslie then argues that by analogy "in the case of generalizations, the unmarked generic
14 invokes the cognitive system's default mode of generalizing. To invoke a nondefault
15 generalization, an explicit and marked quantifier must be used. The connection, then,
16 between generic generalizations and unmarked surface forms is not an accidental one, but
17 rather reflects a deep fact about human cognition. It is no coincidence that no human
18 language has a dedicated, articulated generic operator". (Leslie 2008: 24)

19
20
21
22 This claim seems to rest on the observation that in English, generic generalisations are
23 often expressed with statements that involve a bare plural subject and a simple present
24 predicate and are thus shorter and morphologically simpler than quantified statements.

Except for the Chomsky citation, no definition of markedness is given. Intuitively, it seems that what is at stake is what Haspelmath (2006) discusses as formal markedness, i.e. surface level overt realisation of the type "in English, the past tense is marked (by -ed) and the present tense is unmarked". This seems to work well for English bare plural generics compared to quantifiers like 'all' (compare 'birds fly' to 'all birds fly'). However, it is not clear how it works for the other types of generics in English (indefinite singular, e.g. 'a cat has whiskers' and definite singular, e.g. 'the cat has whiskers') compared to quantifiers ('some cats have whiskers').

The claims that "there is no language that has a 'generic' article, that is, an article which is used exclusively with generic NPs" (Dahl, 1995, p. 425) and that "generics have the tendency to employ the least marked tense-aspect choice in the language" (Dahl, 1995, p. 415) have proven critical for theories of generics despite the fact that the typology of genericity has rarely been tackled systematically (see though Dahl, 1985; Behrens, 2000, 2005; Dayal, 2004). More importantly, in the generics-as-default view these two claims are erroneously confounded into a single claim that generics assume the most unmarked form in the *nominal* domain (Leslie, 2007). This proposal seemingly offers a nice solution to how English learning children can master the distinction between generic and universal or specific statements at an early age (Gelman, 2010, see Lazaridou-Chatzigoga, Katsos, & Stockall, 2015, for discussion). However, while intuitive, this appeal to markedness fails to extend to a

wide range of languages, many of which do *not* use a simpler form for expressing generic generalisations.

Without a clear and robust definition of markedness and a systematic examination of the form of generics alongside quantification and definiteness cross-linguistically, the appeal to unmarkedness and hence to defaultness for generics is impossible to evaluate. Focusing on languages that employ the presence/absence of a determiner in combination with tense/aspect features to express genericity, we observe that Greek differs from English in using a definite plural as the most frequent form for generics (see e.g. Marmaridou-Protopapa, 1984; Roussou & Tsimpli, 1994; Giannakidou & Stavrou, 1999, Lazaridou-Chatzigoga, 2009; Giannakidou, 2012), while bare plural generics in the preverbal position are generally disallowed:

- (8) I tighris ehun righes.
 the.PL tigers have.PL stripes
 ‘Tigers have stripes.’
- (9) *Tighris ehun righes.
 tigers have.PL stripes

Superficially, we already observe that the unmarkedness claim for generics does not hold cross-linguistically if we take it to be formal markedness in the sense of Haspelmath (2006). If we compare *i tighris ehun righes* (‘tigers have stripes’) to *kathe tighri ehi righes* (‘every tiger has stripes’) or to *merikes tighris ehun righes* (‘some tigers have stripes’) we observe that the generic statement is not less marked than a quantified statement. Not only are generics more ‘marked’ in Greek than in English (and in this respect, Greek is similar to Romance languages like French or Spanish, see e.g. Vergnaud & Zubizarreta, 1992; Longobardi, 2001; Chierchia, 1998; Dayal, 2004; Ionin and Montrul, 2010), but also *i tighris ehun righes* is potentially ambiguous between a generic and a definite (anaphoric) interpretation. Given that it can also mean ‘the (contextually salient and previously mentioned) tigers have stripes’, the generic form is not superficially differentiated from the anaphoric form.

Of course, one could also argue for another definition of markedness, according to which something is unmarked if it lacks a dedicated marker in a language. In this sense, Greek generics might still be argued to be unmarked as there is no dedicated marker of genericity in this language. Nevertheless, as we pointed out, without a clear and principled definition of (un)markedness, the appeal to unmarkedness and hence to defaultness for generics is

1
2
3 impossible to evaluate, and there is a danger of selecting whatever sense of markedness
4 happens to fit a given dataset. Our Greek experiment (Experiment 2) offers a comparison
5 between the processing of generic and universally quantified statements in a language where
6 generalisations do not differ in formal markedness, thereby providing some initial data to
7 address the issue.
8
9
10
11
12

13 To recapitulate, (a) the contextual manipulations used in our experiment were expected to
14 make the implicit domain restriction explicit and salient to the participants, (b) this
15 manipulation was expected to influence truth-value judgements of universal generalisations
16 by showing a decrease in acceptance rates in the contradictory condition and an increase in
17 acceptance rates in the supportive condition, and (c) the context effects were expected to be
18 different for different determiners, depending on their semantics and their sensitivity to QDR.
19 We also checked whether our context manipulation would work in a language other than
20 English by running the same study in Greek. By doing so, we addressed one interpretation of
21 the unmarkedness claim for generics and we highlighted the importance of doing
22 experimental work on genericity and quantification cross-linguistically.

34 5.1.1 Participants and procedure

35
36
37
38
39
40
41
42
43 120 volunteers (49 male, 70 female, 1 other; aged 19-67; mean age 37.28; SD 13.06)
44 participated in the experiment over the Internet. Participants were recruited through
45 Amazon's MTurk system for human interface tasks. All spoke English as their first language
46 and lived in the United States. All participants provided their informed consent and received
47 payment. The study met the guidelines for ethical research with human participants of the
48 Department of Theoretical and Applied Linguistics, University of Cambridge.
49
50 The study was presented in the online platform Qualtrics. Each trial consisted of three
51 displays: (1) participants read a background context, (2) they read a statement, and (3) they
52 were asked to judge whether they agreed with the statement they just read. Their response
53 was recorded by selecting keyboard keys ('A' for yes; 'K' for no).

60

5.2 Materials and design

Participants judged 84 statements, including 48 fillers presented in a randomised order. The 12 test items consisted of majority characteristic statements like ‘tigers have stripes’ and ‘horses have four legs’. We included 24 control items, 12 definitional statements like ‘ants are insects’ and 12 false generalisations like ‘books are paperbacks’ to obtain baseline measures and to (semi)-counterbalance the percentage of expected ‘true’/ ‘false’ responses. All the contexts and items were normed beforehand by English native speakers, who did not take part in the experiment. Norming tested whether there was any unknown vocabulary and whether the context-statement pairings sounded natural, that is, if the manipulations worked as intended. Debriefing after norming clarified any additional comments. Some minor adjustments were made afterwards before the items were finalised for the final experiment. Most experimental items were a subset of the items used by Leslie et al. (2011). The two conditions we manipulated for the majority characteristic items were:

- a. determiner type: bare plural generic/ ‘all’/ ‘all the’/ ‘each’
- b. context type: neutral/ contradictory/ supportive.

We varied the context preceding the critical utterance as follows: a) neutral, where the information in the context does not interact with the truth value of the critical statement, b) contradictory, where exceptions which should rule out a universally quantified statement are made salient, and c) supportive, where the generality of the critical property is made salient through a paraphrase. The statements were in one of the four determiner forms and were preceded by one of three levels of context (neutral/contradictory/ supportive), examples of which can be found in (5) above. We deliberately never used the same words to describe the relevant characteristic in our contexts and in the statement we asked participants to evaluate. For instance, our participants would have to infer from the claim in the contradictory context that the specific tigers’ ‘fur is all white’ that they ‘do not have stripes’ or in the supportive context that the ‘black and orange coats’ is a paraphrase of ‘have stripes’. We were keen to avoid priming the ‘tiger/stripes’ lexical association by repetition.

Given the 4 determiners (generic/ ‘all’/ ‘all the’/ ‘each’) we created 4 lists with 3 sublists each that varied with respect to the pairing of the items with context type, which gave us 12

lists in total. 10 participants were assigned randomly to each of the 12 lists. In (11) we see a sample of a trial of a statement with ‘all’ after a neutral context:

(10)

DISPLAY 1:

Background:

Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose playful games visitors love to watch and photograph.

DISPLAY 2:

Statement: All tigers have stripes.

DISPLAY 3:

Do you agree with the statement?

Yes (A) No (K)

The definitional and false generalisations were in the generic form in all lists. Fillers served to ensure the percentage of expected ‘true’/ ‘false’ responses was similar. The definitional and false generalisations, as well as the fillers, were preceded by a context that did not vary across conditions. All materials can be found in Appendix A in the Supplementary Material.

5.3 Results and discussion

The final analysis included 116 participants. Four participants were excluded as they responded correctly to fewer than 10 out of the 12 definitional statements.

Table 1 summarises the proportion of ‘yes’ responses to the TVJ question for the test items (majority characteristic statements) in each condition. We report proportion of ‘yes’ responses rather than the actual number of responses to facilitate comparison with Leslie et al.’s (2011) results.

Table 1. Mean Proportion (SE) of ‘yes’ responses as a function of context and determiner type in Exp. 1. The subtractions between the relevant conditions are also given.

Condition	Neutral	Contradictory	Supportive	Contradictory- Neutral	Supportive- Neutral
GEN (\emptyset)	99.14 (3.12)	87.07 (0.86)	100 (0)	-12	1
all	80.56 (3.82)	48.15 (4.83)	87.96 (3.14)	-33	7
all the	78.33 (3.78)	37.50 (4.43)	90 (2.76)	-40	12
each	79.17 (3.72)	30.83 (4.23)	85.83 (3.2)	-48	7

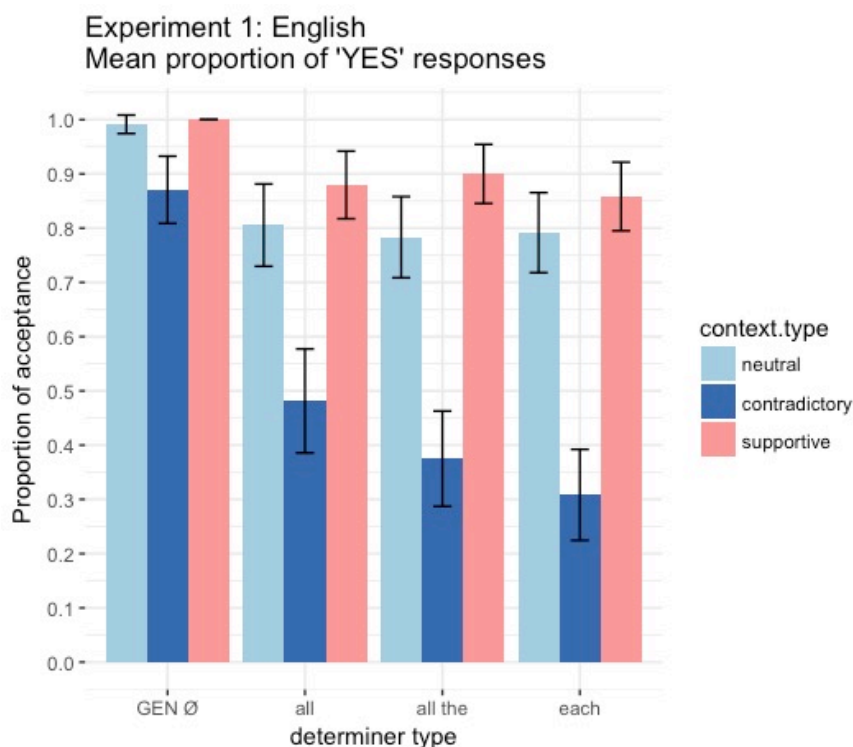

Figure 1. Mean proportion of 'yes' responses as a function of context and determiner type. Error bars represent 95% confidence intervals.

As we see above, overall, generics were accepted at higher rates than universals, as expected, given that we had chosen items that were true in generic form. Both in the neutral and the supportive condition acceptance rates for generics were at ceiling (99% and 100% respectively) and were only lower in the contradictory condition (87%). With universals, the picture is more complicated. All three universals ('all', 'all the', 'each') were accepted at similar rates in both the neutral and the supportive condition, showing only a small increase in the supportive condition. In the neutral condition, 'all'-statements were accepted 81% of the time, 'all the'-statements 78% of the time and 'each'-statements 79% of the time. In the supportive condition, 'all'-statements were accepted 88% of the time, 'all the'-statements 90% of the time and 'each'-statements 86% of the time. Universals after a contradictory context yielded fewer acceptances overall, as expected: 'all'-statements were accepted at 48%, 'all the'-statements at 38% and 'each'-statements at 31%.

We used R (R Core Team, 2016) and the lme4 package (Bates, Maechler, Bolker & Walker, 2015) to perform a generalised mixed-effects linear analysis of the effects of between determiner and context on the yes/no response, specifying a binomial family. Responses were treated as a dummy coded categorical variable and were modelled with

glmer. First, we fitted a full model with `det.type` and `context.type` as fixed effects (with an interaction term) and with random intercepts for subjects and items. We performed a likelihood ratio test of the full model with an interaction term against a model without the interaction term and the comparison proved non-significant ($\chi^2(6) = 8.3455, p = .214$). Including an interaction term did not significantly improve model fit, so we used the model without the interaction term for all subsequent analyses/comparisons.

We then fitted versions of the full model, in which a single effect was removed and we compared the reduced model to the model without interaction. To test the main effect of context, we removed context. A likelihood ratio test of the model without interaction against the model without context proved significant ($\chi^2(2) = 311.81, p < .001$). Thus, we concluded that there was a main effect of context. To test the main effect of determiner, we removed determiner. A likelihood ratio test of the model without interaction against the model without determiner proved significant ($\chi^2(3) = 58.183, p < .001$). Thus, we concluded that there was a main effect of determiner.

As we see in table 2, in the neutral condition, the difference between generics and all universal quantifiers was statistically significant (all $ps < .001$). Generics in the neutral condition are significantly different from generics in the contradictory condition ($p = .004$), but not significantly different from the supportive condition ($p = 0.76$). Thus, manipulating context seems to influence how people interpret generics too, to a certain extent.

Table 2. Estimates, standard errors, z values and p values of the full glmm in Exp. 1.

	Estimate	Std. Error	z value	Pr(> z)
Intercept (generic, neutral)	5.8432	1.1150	5.241	1.6e-07 ***
det (all)	-3.9450	1.1708	-3.369	0.000753 ***
det (all the)	-4.0789	1.1615	-3.512	0.000445 ***
det (each)	-3.9228	1.1636	-3.371	0.000748 ***
context (contradictory)	-3.1623	1.0847	-2.915	0.003553 **
context (supportive)	13.7194	44.9064	0.306	0.759978
det x context (all, contradictory)	1.1622	1.1434	1.016	0.309411
det x context (all the, contradictory)	0.6892	1.1392	0.605	0.545210
det x context (each, contradictory)	0.0946	1.1473	0.082	0.934285
det x context (all, supportive)	-13.0339	44.9071	-0.290	0.771631
det x context (all the, supportive)	-12.4670	44.9084	-0.278	0.781312
det x context (each, supportive)	-13.1128	44.9067	-0.292	0.770285

Moving now to the universal quantifiers. On the surface, we do obtain many ‘yes’ responses to universal quantifiers, as in the generics-as-default literature. We predicted that, across the board, contradictory context should decrease acceptances, while supportive context should increase them. More importantly, we had specific predictions about the relative rates between the universal quantifiers depending on their sensitivity to QDR, which the default generic bias cannot predict. In order to appreciate the relative effect of context on acceptance rates, we subtracted the average means of the neutral condition from the average means of the contradictory and supporting conditions. We interpreted the rates obtained as the relative effect of context on acceptance rates plotted in Fig. 2 below.

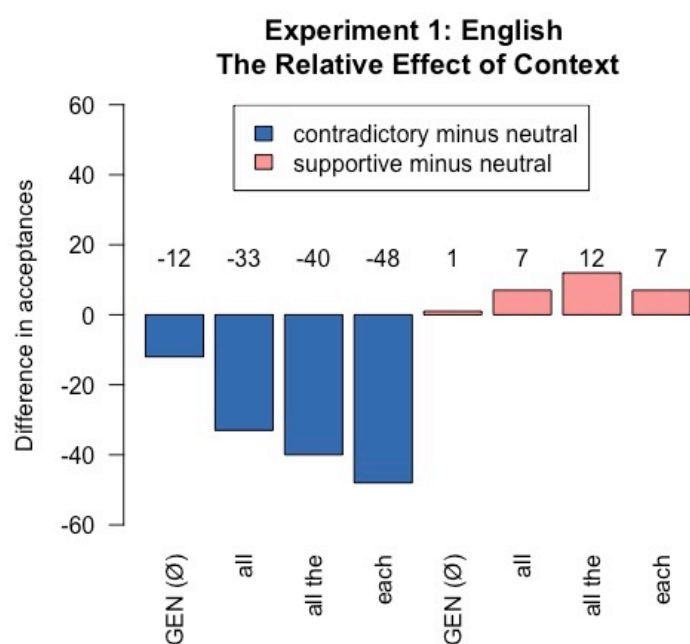

Figure 2. The relative effect of context in Exp. 1. Acceptance rates in the neutral condition are plotted with the baseline condition as 0. Negative values show the subtracted average means of the neutral condition from the average means of the contradictory condition and positive values show the subtracted average means of the neutral condition from the average means of the supportive condition.

In a second planned analysis, seen in table 3, we were interested in planned comparisons between the different universal quantifiers. We built a model only with the universal quantifiers, ‘all’, ‘all the’ and ‘each’. We first looked at effects related to ‘all’ and the three levels of context. ‘All’ in the neutral context differed significantly from ‘all’ in the contradictory context ($p < .001$), but not from ‘all’ in the supportive context ($p = .112$). We then looked at effects related to ‘all the’ and the three levels of context. ‘All the’ in the

neutral context differed significantly both from ‘all the’ in the contradictory context ($p < .001$), and ‘all the’ in the supportive context ($p = .004$). ‘Each’ in the neutral condition differed significantly from ‘each’ in the contradictory context ($p < .001$), but not from ‘each’ in the supportive context ($p = .145$). In the neutral condition, there were no significant differences between ‘all’ and ‘all the’ ($p = .809$) or between ‘all’ and ‘each’ ($p = .961$). In the contradictory condition, ‘all’ differed significantly from ‘each’ ($p = .038$), but not from ‘all the’ ($p = .221$). In the supportive condition there were no significant differences between ‘all’ and ‘each’ ($p = .918$) nor between ‘all’ and ‘all the’ ($p = .488$).

Table 3. Estimates, standard errors, z values and p values of the glmm without generics in Exp. 1.

	Estimate	Std. Error	z value	Pr(> z)
Intercept (all, neutral)	1.90580	0.42752	4.458	8.28e-06 ***
det (all the)	-0.13329	0.55003	-0.242	0.8085
det (each)	0.02695	0.55556	-0.049	0.9613
context (contradictory)	-2.00459	0.37130	-5.399	6.70e-08 ***
context (supportive)	0.68454	0.43037	1.591	0.1117
det x context (all the, contradictory)	-0.47904	0.51241	-0.935	0.3499
det x context (each, contradictory)	-1.07973	0.52983	-2.038	0.0416 *
det x context (all the, supportive)	0.57050	0.61347	0.930	0.3524
det x context (each, supportive)	-0.08964	0.59212	-0.151	0.8797

Thus, we obtain the effect for the contradictory context exactly as predicted for the universal quantifiers. The relative effect is bigger for those quantifiers that require QDR because of their semantics (‘all the’, ‘each’) than for the one that allows but does not require it/may resist it (‘all’). The prediction about the supportive context was not borne out except for ‘all the’, where we do see a significant increase compared to the neutral condition. Adding explicit information supporting the statement hardly mattered, as acceptances did not rise significantly (increase of 1% for generics, 7% for ‘all’, 7% for ‘each’), except for ‘all the’ at 12%. The high acceptance rates in the neutral condition are possibly due to participants being charitable and/or exceptions not being immediately salient. The atypical nature of ‘all’ does not seem to be a likely explanation of the GOG effect given that the differences in acceptances across quantifiers in the neutral condition were minimal, that is, the difference between ‘all’ and ‘all the’ was 3% and the difference between ‘all’ and ‘each’ was 2%.

Regarding our control items, across participants, acceptance rates for definitional statements were almost at ceiling, at 97%, while false generalisations were rejected most of

1
2
3 the time with acceptance rates at 31%. These results were as expected and are in line with
4 previously discussed rates in the literature (e.g. Leslie et al., 2011, report 90% and 38%
5 acceptance respectively in their experiment 1).
6
7

8 An outstanding issue is why there were any acceptances in the contradictory condition
9 for ‘all the’ and ‘each’ given the prediction that participants have to necessarily restrict their
10 interpretation to the counterexamples given in the discourse. These acceptances (at 38% for
11 ‘all the’ and at 31% for ‘each’) could still be interpreted by proponents of the generics-as-
12 default view as instances of a GOG effect. We believe though, that in order to conclude that
13 there is such an effect, one must not only point out that there are still acceptances that are not
14 accounted for by domain restriction, but also to rule out other already existing alternative
15 explanations too. Invoking the other factors that might influence ‘all’ is not a viable option
16 for ‘all the’ or ‘each’, because the subkind interpretation is illicit and their meaning is not
17 prone to hyperbolic/loose interpretation. Some of these acceptances might be potentially
18 attributed to the strong association between the concept TIGER and the concept STRIPE (see
19 footnote 3). This though would also mean that participants were not actually parsing the
20 statements as a whole within a context, but they were only focusing on the lexical meaning of
21 the words involved, which is highly unlikely given the differences between conditions.
22
23

24 Other factors that contribute to the non-zero acceptances are outlined here: (a)
25 participants’ acceptances of false fillers such as ‘London is in Egypt’, which were non-
26 quantified statements concerning factual knowledge, were at 7% suggesting that a new
27 baseline should be drawn treating 7% of acceptances across the board as pure errors (e.g. due
28 to participants being inattentive, pressing the incorrect key, etc.), that is, if 7% of these
29 acceptances were errors, we are left with 31% for ‘all the’ and 24% for ‘each’ to be
30 accounted for, (b) participants’ acceptances of false, non-quantified generalisations such as
31 ‘animals are reptiles’ or ‘books are paperbacks’ at 31% further indicates that people generally
32 find judging these kind of statements difficult. This suggests again that the actual baseline
33 error rate is higher.
34
35

36 Two independent phenomena, quite broadly attested in the literature, might have also
37 influenced these acceptances: (a) the *acquiescence bias*, i.e. the tendency to endorse an
38 assertion made in a question regardless of the assertion’s content (Krosnick & Presser, 2010),
39 and (b) participants are known to be pragmatically charitable (Grice, 1975), thus they would
40 try to find an interpretation that would render the statement ‘true’ even despite the salient
41 context (see for instance Chemla and Bott, 2013, for the relevance of charitable interpretation
42 in pragmatic reasoning).

Discussion of Experiment 1

We set out to explore one of the alternative explanations for the judgement data that concern universally quantified statements, which have been used as evidence of a GOG effect. The present study provides experimental evidence for the relevance of a QDR-based explanation for much of the attested behaviour. In our study, context did not only affect acceptance rates for ‘all’, ‘all the’, ‘each’, but it further predicted the levels of QDR depending on the level of context. The effect of context was greater for ‘all the’ and ‘each’, two quantifiers that require QDR, while it was smaller for ‘all’, whose domain is only optionally restricted and may resist it. This leads us to conclude that Leslie et al. (2011) prematurely understated the relevance of context as a principled way of explaining the attested behaviour. Furthermore, even though they only discuss ‘all’ they make general claims about (universal) quantification being prone to the GOG effect. We argue that drawing conclusions about universal quantification (and by extension about genericity) requires more subtle manipulations. The differences we found between the different universal quantifiers are predicted according to the QDR view advanced here. We also find that manipulating context seems to affect generics to some extent too. This seems contrary to the received view that takes generics to strictly resist contextual narrowing (Krifka, 1987) but is in line with recent work arguing that generics display some context sensitivity (see Sterken, 2015, and references therein). An explanation for this result is offered in the general discussion (section 7).

6. Experiment 2: Generalisations in Greek

With respect to generics in Greek, as discussed in section 4, a statement like *i tighris ehun righes* ‘DET tigers have stripes’ is potentially ambiguous between a generic and a definite (anaphoric) interpretation. Given this ambiguity, one might expect fewer acceptances of ‘generics’ in Greek across the board. In the neutral and supportive contexts both interpretations would give rise to the same target response. Judging *i tighris ehun righes* after a neutral context, one should accept it in both cases: (a) under a generic interpretation, they should judge it as ‘true’ given that they know that this is a characteristic of tigers that holds in general, and (b) under an anaphoric interpretation, they should judge it as ‘true’ given that they have no reason to assume that the specific tigers mentioned in the discourse are not normal instances of tigers. Judging *i tighris ehun righes* after a supportive context, one is

1
2
3 expected to accept it in both cases too: (a) under a generic interpretation, for the same reason
4 as above, and (b) under an anaphoric interpretation, they should judge it as ‘true’ given that
5 the context provides them with positive information about the property in question. Because
6 the supportive context explicitly licences the anaphoric interpretation, we expect higher
7 acceptance rates in this context compared to the neutral. The expected response only differs
8 in the case of the contradictory context depending on what interpretation one assigns to the
9 statement: (a) under a generic interpretation, one is expected to accept it given that generics
10 tolerate exceptions, but (b) under an anaphoric interpretation, one is expected to reject it
11 given that the individuals introduced in the discourse lack the relevant property. In the
12 contradictory context, we expect lower acceptances than both neutral and supportive
13 contexts.
14
15
16
17
18
19
20
21

22 A related prediction concerns the issue of whether there is a preference for the generic
23 over the definite (anaphoric) interpretation in Greek. Previous research on Spanish definite
24 plural generics (Ionin and Montrul, 2010), which, like Greek, are ambiguous between a
25 generic and an anaphoric interpretation, finds that Spanish native speakers were far more
26 likely to interpret such statements as generic (81%) than anaphoric after a context that was
27 similar to our contradictory context, irrespective of whether it made the statement ‘true’ or
28 ‘false’. Regardless of whether that preference was a task-related effect, a possibility the
29 authors acknowledge, it is worth-while investigating whether such a bias exists in Greek too.
30
31
32
33
34
35

36 With respect to universals, according to the generics-as-default view, given that
37 generics are the default way children and adults generalise, the tendency to overgeneralise
38 when it comes to universals ought to be universal. Thus, speakers of languages other than
39 English might also be prone to make erroneous judgments concerning universal
40 generalisations under some circumstances.
41
42
43
44

45 Cross-linguistic evidence can additionally tackle the issue of whether the effect is due
46 to the atypical behaviour of the English quantifier ‘all’. Although *oli i* contains the definite
47 article, this quantifier behaves similarly to the English quantifier ‘all’ and not to ‘all the’ (see
48 Tsili, 2001; Tsamadou-Jacobberger, 2006; Giannakidou, 2012). For instance, *oli i* can be used
49 to refer to either all students in general (*oli i mathites latrevun tis diakopes* ‘all students love
50 holidays’) or it can be contextually restricted to a specific set of students (*oli i mathites*
51 *hamoghelusan* ‘all the students were smiling’). Thus, Greek differs from English in that it
52 does not have two versions of the quantifier ‘all’. The Greek quantifier *oli i* optionally allows
53 restriction. Participants who accept a statement like ‘all tigers have stripes’ in Greek might be
54 applying QDR to the quantifier. However, as is the case with ‘all’, there are other alternative
55
56
57
58
59
60

1
2
3 explanations which might lead someone to accept a statement with *oli i*: (a) ignorance and/or
4 (b) the subkind interpretation. The generics-as-default view, in contrast, has no principled
5 way of explaining any potential differences in acceptance rates depending on the level of
6 context (neutral, contradictory, supportive) for *oli i* ‘lit. all the’ any more than it does for
7 ‘all’.
8
9

10 11 12 13 6.1 Method

14 15 16 6.1.1 Participants and procedure

17
18
19
20 60 volunteers (47 female; aged 19-71; mean age 36.28; SD 16.08) participated in the
21 experiment over the Internet. Participants were recruited through mailing lists and word of
22 mouth. All spoke Greek as their first language and provided their informed consent to enter a
23 prize draw. The study followed the same guidelines and used the same procedure as
24 Experiment 1, except that it was in Greek and only compared generics (definite plurals) to
25 one type of universal quantifier (*oli i* ‘all’).
26
27
28
29
30
31

32 6.2 Materials and design

33
34
35 Participants judged the same set of 84 statements as in Experiment 1, including 48 fillers
36 presented in a randomized order. The 12 test items of majority characteristic statements were
37 exactly the same. The 24 control items (12 definitional statements and 12 false
38 generalisations) were the same except for four items, which were replaced in order to sound
39 more natural in Greek. Given the potential ambiguity between an anaphoric and a generic
40 interpretation of a definite plural, the contexts for the false generalisations were modified in
41 order to bias participants towards a generic interpretation. As in the English experiment, all
42 the contexts and items were normed beforehand by Greek native speakers, who did not take
43 part in the experiment. The two conditions we manipulated for the majority characteristic
44 items were:
45
46
47
48
49
50
51
52
53

- 54 a. determiner type: definite plural generic/*oli i* ‘all’
 - 55 b. context type: neutral/contradictory/supportive
- 56
57
58
59
60

Given the 4 determiners (*generic/all/all the/each*) we created 2 lists with 3 sublists each that varied with respect to the pairing of the items with context type, which gave us 6 lists in total. 10 participants were assigned randomly to each of the 6 lists.

6.3 Results and discussion

The final analysis included 57 participants. Three participants were excluded as they responded correctly to fewer than 10 out of the 12 definitional statements.

Table 4 summarises the proportion of ‘yes’ responses to the TVJ question for the test items (majority characteristic statements) in each condition and Fig. 3 plots these results graphically.

Table 4. Mean Proportion (SE) of ‘yes’ responses as a function of context and determiner type in Exp. 2. The subtractions between the relevant conditions are also given.

Condition	Neutral	Contradictory	Supportive	Contradictory- Neutral	Supportive- Neutral
GEN (i)	92.24 (2.49)	76.72 (3.94)	95.69 (1.89)	-15	4
oli i	70.54 (4.33)	51.79 (4.74)	78.57 (3.89)	-19	8

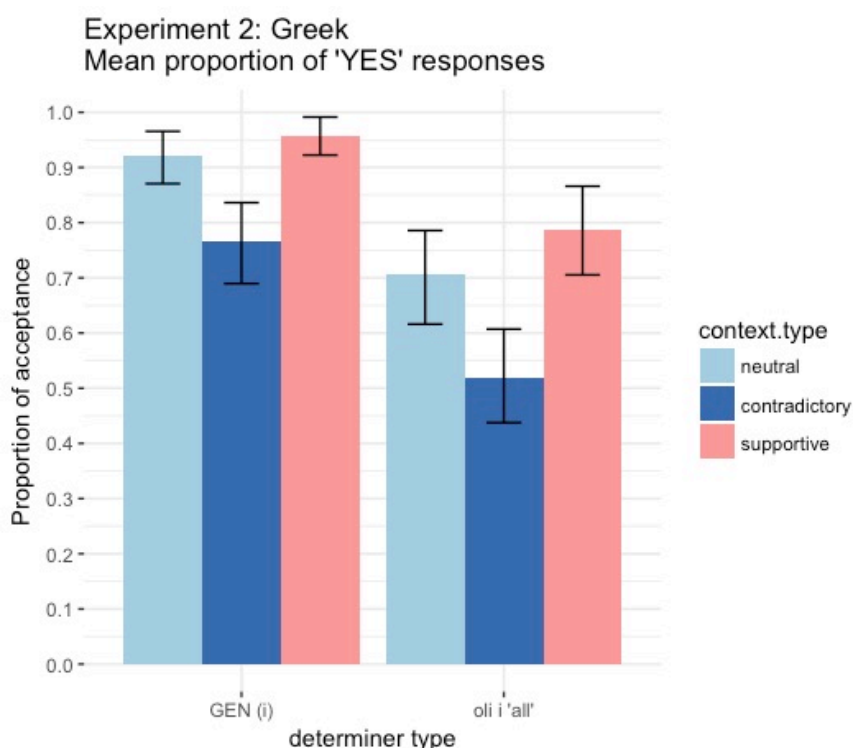

Figure 3. Mean Proportion of ‘yes’ responses as a function of context and determiner type. Error bars represent 95% confidence intervals.

1
2
3 As we see above, generics were accepted at higher rates than universally quantified
4 statements with *oli i* ‘all’ across the board. This was as expected both for the neutral and the
5 supportive conditions given that both possible interpretations of the nominal
6 (generic/anaphoric) render the statements ‘true’. Thus, generics were judged as true at very
7 high rates (92% in the neutral and 96% in the supportive condition). Acceptance was lower in
8 the contradictory condition, at 77%. This was expected, given that one of the interpretations
9 (the anaphoric one) made the statement false. Even though the anaphoric interpretation was
10 the most salient one for this task, our findings seem to support a strong preference for the
11 generic reading at rates similar to the ones observed for Spanish (Ionin and Montrul, 2010).
12 Universals with *oli i* ‘all’ were accepted at 71% in the neutral condition and at 79% in the
13 supportive condition. Acceptances in the contradictory condition were at 52%. These
14 differences in acceptances of the universally quantified statements show that context is a
15 major licenser of the attested behaviour.

16
17 We followed the same procedure we used for English to analyse the Greek data. First,
18 we fitted the full model with *det.type* and *context.type* as fixed effects (with an interaction
19 term) and *subject* and *item.no* as random effects – see table 6 below. After building the full
20 model, we built a model with the same fixed and random effects, but without an interaction
21 term. We performed a likelihood ratio test of the full model with an interaction term against
22 the model without the interaction term and the comparison proved non-significant ($\chi^2(2) =$
23 $1.343, p = .51$). Thus, adding an interaction term did not significantly improve model fit, so
24 we used the model without the interaction term for all subsequent analyses/comparisons.

25
26 We then fitted versions of the full model, in which a single effect was removed and
27 we then compared the reduced model to the model without interaction. In order to test the
28 main effect of context, we removed *context.type*. We performed a likelihood ratio test of the
29 model without interaction against the model without *context.type* and the comparison proved
30 significant ($\chi^2(2) = 58.824, p < .001$). Thus, we concluded that there was a main effect of
31 context. In order to test the main effect of determiner, we removed *det.type*. We performed a
32 likelihood ratio test of the model without interaction against the model without *det.type* and
33 the comparison proved significant ($\chi^2(1) = 17.544, p < .001$). Thus, we concluded that there
34 was a main effect of determiner.

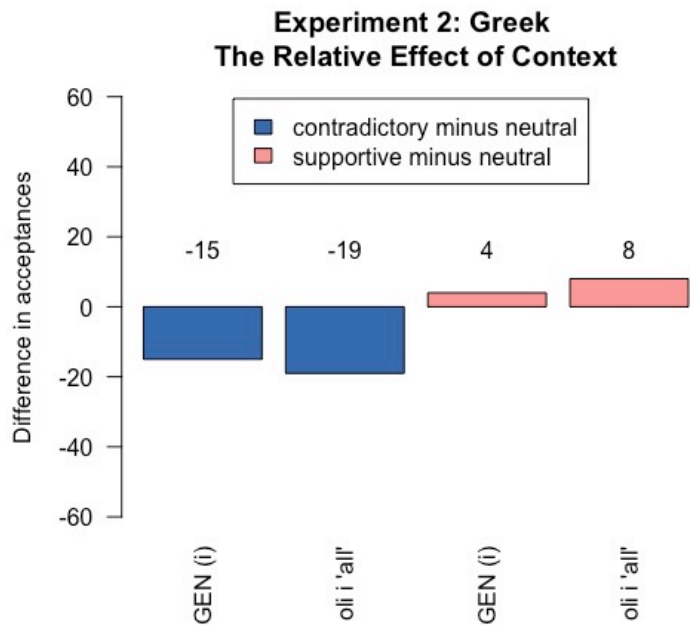

35
36 As we see in table 5, focusing on the neutral condition, generics differ significantly
37 from *oli i* ($p < .001$). Focusing on generics in different levels of context, the difference
38 between the generic neutral is significantly different from the generic contradictory ($p <$
39 $.001$), but not between the generic neutral and the generic supportive ($p = .11$). Focusing on
40

the universal *oli i* and the different levels of context, the difference between *oli i* neutral and *oli i* contradictory is significant ($p < .001$), while the difference between *oli i* neutral and *oli i* supportive is not significant ($p = .055$).

Table 5. Estimates, standard errors, z values and p values of the full glmm in Exp. 2.

	Estimate	Std. Error	z value	Pr(> z)
Intercept (generic, neutral)	3.7630	0.6698	5.618	1.93e-08 ***
det (<i>oli i</i>)	-2.3895	0.6752	-3.539	0.000401 ***
context (contradictory)	-1.7637	0.5090	-3.465	0.000530 ***
context (supportive)	1.1032	0.6897	1.599	0.109721
det x context (<i>oli i</i> , contradictory)	0.4620	0.6226	0.742	0.458100
det x context (<i>oli i</i> , supportive)	-0.3217	0.7943	-0.405	0.685498

For universals, we obtained many ‘yes’ responses to *oli i* ‘all’ statements ranging from 79% (supportive) to 71% (neutral) and 52% (contradictory). These data would most probably be attributed to a GOG effect by proponents of the generics-as-default view. Nevertheless, we believe that it is important to focus first on the quantifier’s sensitivity to QDR. In the Greek design we did not have any quantifier that required QDR. *Oli i* ‘all’ does not require QDR, but optionally allows it. Plotting in Fig. 4 below the relative effect of context we note that the differences between the different levels of context for *oli i* ‘all’ are in the direction expected given the results of Experiment 1, with fewer acceptances in the contradictory condition and more acceptances in the supportive condition. The participants who accept a statement like ‘all tigers have stripes’ in Greek might have done so because of the following reasons: (a) the available option for QDR for *oli i* ‘all’, (b) because they used a subkind interpretation or (c) because they were ignorant of the facts.

25 Figure 4. The relative effect of context in Exp. 2. Acceptance rates in
26 the neutral condition are plotted with the baseline condition as 0.
27 Negative values show the subtracted average means of the neutral
28 condition from the average means of the contradictory condition and
29 positive values the subtracted average means of the neutral condition
30 from the average means of the supportive condition.
31
32
33

34 We observe an interesting difference if we compare the English 'all' results to the
35 Greek *oli i* 'all' results. The relative effect of context in the contradictory condition seems
36 bigger in English, with a decrease of 33% compared to the neutral condition, than in Greek,
37 where the decrease is 19%. Focusing on the raw scores though reveals that acceptance rates
38 are similar in both languages in the contradictory condition (at 48% for English and 52% for
39 Greek), but there are far fewer acceptances for *oli i* in the neutral condition (71%) than for *all*
40 (81%), leading to a smaller relative effect for the context manipulation. We could attribute
41 this to the presence of the control items, which used definite plurals in Greek, which are
42 potentially ambiguous in Greek but not in English, as discussed above. Greek participants
43 might have been more aware of multiple interpretations of a given statement than their
44 English counterparts, even in the neutral condition, and thus less prone to accept the
45 statements.
46
47
48
49
50
51
52
53
54

55 Moreover, Greek generics are more affected by the context manipulation than English
56 generics, as expected given the potential ambiguity in Greek. Acceptances in the neutral
57 condition are less common in Greek (92%) compared to English (99%) and the relative effect
58
59
60

1
2
3 of context in the contradictory condition is bigger in Greek (a decrease of 19%) than in
4 English (a decrease of 12%).

5
6 Regarding our control items, across participants definitional statements were accepted
7 96% of the time and false generalisations were accepted 7% of the time. The contexts for
8 false generalisations were different from the English ones (where acceptances were at 31%),
9 as the context in Greek was biased towards a generic interpretation (in order to rule out the
10 anaphoric interpretation of the statement). This might have made other subkinds of the
11 relevant kind more salient and so rejecting the statement was facilitated for Greek
12 participants.

13
14 To sum up, experiment 2 addressed one interpretation of the unmarkedness claim with
15 respect to generics and showed that the picture is more complicated as soon as one moves
16 from English to a language like Greek with a different configuration of nominals involved in
17 genericity, quantification and definiteness. The results confirmed that our context
18 manipulation works in two different languages and that QDR is a viable explanation for
19 much of the purported GOG effect cross-linguistically.

20 21 22 23 24 25 26 27 28 29 30 31 7. General Discussion

32
33 We set out to explore the scope of the purported generic overgeneralisation (GOG) effect, as
34 it has been proposed as one of the main pieces of evidence for the generics-as-default view
35 (Leslie 2007, 2008; Gelman, 2010; Leslie et al. 2011). According to its proponents, this effect
36 concerns participants accepting universally quantified statements such as ‘all ducks lay eggs’
37 and ‘all tigers have stripes’ as true, even though they should reject them as false. The
38 explanation given for the pattern of judgment data observed is that participants fail to
39 properly evaluate the universal statements in question and, erroneously, rely on their
40 judgments of the corresponding generics, in this case ‘ducks lay eggs’ and ‘tigers have
41 stripes’, which are true and tolerant of exceptions.

42
43 The studies presented here show that attributing the attested behaviour to a default
44 overgeneralisation bias such as the GOG effect is not yet fully warranted. We argue that
45 Leslie et al. (2011) ruled out alternative explanations for these data prematurely and we
46 furthermore addressed the size of one of the alternative explanations for the attested
47 behaviour. Our studies provide experimental evidence for the relevance of a QDR-based
48 explanation of much of the behaviour attributed to the GOG effect. In our studies, we focused
49 on majority characteristic statements like ‘all tigers have stripes’ and manipulated context in
50
51
52
53
54
55
56
57
58
59
60

1
2
3 order to show that what is at play is not a generic bias, but people judging the generalisations
4 largely based on what they know about the semantics and pragmatics of genericity and
5 quantification and on independently motivated mechanisms related to these interpretations
6 such as QDR. We used three levels of context: (a) neutral, where the information in the
7 context does not interact with the truth value of the critical statement; (b) contradictory,
8 where an exception which should rule out a universally quantified statement is made salient,
9 and (c) supportive, where a paraphrase of the critical property is given, which makes its
10 generality salient. Based on these three levels of context and the sensitivity to QDR that the
11 universal quantifier used in the critical statement shows, we were able to predict much of the
12 variation in acceptance rates. The context affected acceptance rates for ‘all’ and *oli i* ‘all’ and
13 other universal quantifiers (‘all the’, ‘each’) and thus it predicted the levels of QDR. Our data
14 show that drawing conclusions about universal quantification (and by extension about
15 genericity) requires more subtle manipulations. The differences we found between the
16 different universal quantifiers are predicted according to the QDR view advanced here but are
17 inconsistent with the generics-as-default view, as we understand it. According to the
18 generics-as-default view, the ‘more marked’ System 2 universal statements should be
19 ‘erroneously’ interpreted as generic statements at similar rates, as the attested behaviour is
20 due to an underlying generic bias that involves incorrect processing of the quantifiers and
21 does not depend on the properties of the quantifiers themselves.

59
60
The claim that generics are unmarked compared to quantifiers has also played an
important role in the generics-as-default proposal. We argued that the claim is not well-
substantiated for any language and that without a proper definition of markedness, this claim
is impossible to evaluate. We made a first step towards that direction by looking at a
language where generics are expressed differently than in English. Crucially, for the issue at
hand, if we assume a definition of markedness as formal markedness, i.e. surface level overt
realisation, following Haspelmath (2006), Greek generics are not less marked than quantifiers.
Our results show that the QDR view advanced here correctly predicts the pattern of responses
depending on the type of context and the sensitivity of *oli i* ‘all’ to QDR, whereas the
generics-as-default view has no principled way of explaining the variable acceptance rates
between contexts.

A fact that bears further discussion is what looks like context effects for generics in
English. This seems contrary to the received view that takes generics to strictly resist
contextual narrowing (Krifka, 1987) but is in line with recent work (Sterken, 2015) that
argues that generics may be subject to contextual restriction after all. Looking more closely at

1
2
3 the examples Sterken (2015) discusses reveals that generics' context sensitivity might be tied
4 only to some specific cases and not to all types of generic statements. Sterken's examples
5 highly depend on the context of utterance and the question under discussion e.g. the
6 statement 'dobermans have floppy ears' is true in the context of evolutionary biology, but
7 false in the context of dog breeding. Our materials manipulated context in the sense of
8 making some exceptions salient or not, but we did not introduce different contexts of
9 utterance in the sense described above. Thus, it is not clear that our materials constitute cases
10 of context sensitivity for generics in the sense of Sterken. There are, however, other
11 alternative explanations for the observed behaviour. It might be that the contradictory
12 contexts with the explicit mention of counterexamples made the participants doubt their
13 beliefs with respect to the prevalence of the property in question. Thus, some participants
14 might have (wrongly) updated their belief about the prevalence of the property in order to
15 align with what was given to them in the context of the experiment leading them to reject
16 (true) generic statements in English.

17
18 A further issue to be addressed in future studies is the relevance of the other
19 alternative explanations for the attested behaviour. Even though we have shown that QDR is
20 a major contributing factor in the attested behaviour, the other ways via which people might
21 accept the statements in question still require investigation. In this respect, the subkind
22 interpretation seems particularly relevant and we have argued above (see section 1.2b above)
23 that the way this has been addressed in previous literature is not satisfactory. It is important to
24 note that all the statements used here and in related studies are about animals, which belong
25 to natural kinds. Natural kinds lend themselves easily to a subkind interpretation, as people
26 know that animals have different subspecies and belong to a well-described biological
27 classification (see e.g. the Linnaean taxonomy). It is easy to imagine different subkinds of
28 tigers that all belong to the kind tiger, which is characterised by the property of having
29 stripes. Or that different subkinds of ducks all have in common the fact that they lay eggs. A
30 future study could address the relevance of the subkind interpretation, as it is interesting to
31 understand the degree to which these phenomena are tied to animal kinds, for which a
32 characterisation at species level is readily available alongside different subkinds. In table 6
33 we summarise the alternative explanations to the GOG effect ordered by effect size.

Table 6. Alternative explanations to the GOG effect ordered by effect size.

Explanation	Study	Quantifier	Effect Size		Comment
1. Quantifier Domain Restriction	Our experiments		majority		
	English	‘all’	-33%		Difference in acceptances between the neutral and the contradictory condition
	English	‘all the’	-40%		
	English	‘each’	-48%		
	Greek	‘oli i’	-19%		
	Leslie et al. (2011)	‘all’	majority	minority	
			-18%	-21%	Difference in acceptances between exp. 1 and 2a
	Leslie et al. (2011)	‘all’	-1.6%		Paraphrases including subset restriction in exp. 2b
2. Ignorance	Leslie et al. (2011)		majority	minority	
		‘all’	+20%⁷	-19%	Difference in acceptances between exp. 3a and 3b
3. Error	Our experiments				
	English	no Q	6.67%		Acceptances of false fillers
	Greek	no Q	5.45%		
4. Atypical ‘all’	Our experiments	‘all the’ vs. ‘all’	-3%		Acceptances in the neutral condition
		‘each’ vs. ‘all’	-2%		
5. Subkind interpretation	Leslie et al. (2011)	‘all’	-1%		Paraphrases including subtypes in exp. 2b

If each of these factors contributes independently and cumulatively to the ‘erroneous’ acceptance rates for universally quantified generalisations characterised as GOG errors in the literature, the entirety of the 78% acceptance rate for universally quantified majority

⁷ See Leslie et al (2011) and discussion in Lazaridou-Chatzigoga, Stockall, & Katsos (2017) for consideration of this surprising *increase* in the rates at which statements such as ‘all tigers have stripes’ were accepted as true when the participants performed the knowledge task before evaluating the statements. It is important to note that the knowledge task failed to test whether participants are aware that majority characteristic statements also have exceptions, that is, participants in the knowledge task were not asked to judge whether ‘albino tigers have stripes’ or ‘amputated horses have four legs’, but were only asked to judge false minority characteristic statements such as ‘male ducks lay eggs’.

1
2
3 characteristic statements in Leslie et al.'s (2011) experiment 1 could be explained by these
4 factors, with hardly any residue requiring a GOG explanation. Our key claim is that such
5 alternative explanations need to be seriously entertained, and systematically evaluated, before
6 invoking a GOG effect. In the future, a careful experimental examination of all the other
7 known semantic and pragmatic factors that independently lead to behaviour similar to the
8 GOG effect will help to properly evaluate the contribution of the GOG effect on the
9 interpretation of universal statements.

10
11
12
13
14
15 Another crucial aspect that deserves closer attention in future studies is acceptance
16 rates per item. The previous literature does not report these, but it is important to note that in
17 our studies we do find that some items are accepted/rejected more easily than others. For
18 example, 'all butterflies have wings' is accepted 75% of the time in the contradictory context,
19 despite the context specifically discussing injured, wingless butterflies, while 'all leopards
20 have spots' is only accepted 11% of the time in this condition. Similar item specific variation
21 is also found for the other quantifiers, and in the Greek data set. It is not obvious what could
22 be driving such differences.

23
24
25
26
27
28
29 In sum, we argue that two central assumptions/ingredients of the generics-as-default
30 view, the generic overgeneralisation effect and the unmarkedness claim, have to be
31 scrutinised in studies that manipulate additional factors and to be tested cross-linguistically.
32 The general thrust of this work is that, rather than being under the influence of a blanket
33 default bias that covers all cases across the board, adult participants who make these
34 judgements are largely sensitive to the subtle interplay of quantifier semantics and pragmatics
35 on the one hand, and context on the other. This approach has the advantage of accounting for
36 big portions of the attested data by means of an independently motivated factor, QDR,
37 without the need to postulate a new mechanism such as the GOG effect which is specifically
38 at play exclusively for universal generalisations.

39
40
41
42
43
44
45
46 The present data serve as the first demonstration of how an interdisciplinary
47 programme that brings systematicity and consistency to the study of generics and universals
48 across a range of diverse domains of inquiry can significantly advance our understanding of
49 how we make generalisations and how we express them in language. They also suggest more
50 directions for future investigation. By broadening the investigation of generic and universal
51 generalisations to languages other than English, we can clarify the language-specific and
52 language-general features of generics. It will also be important to address the nominal system
53 in the language under investigation more broadly, as the interplay of genericity,
54 quantification and definiteness seems to have repercussions for the availability of certain
55
56
57
58
59
60

1
2
3 interpretations. Finally, the present research raises the question of what factors more
4 generally influence the way people express and understand generalisations by drawing
5 special attention to pragmatic reasoning and linguistic knowledge of the system of the
6 language in question.
7

3 Appendix A

4 Materials for Experiments 1 and 2. Contexts did not vary across determiner types. The
5 statements are given here in the generic form. Most of the statements are a subset of the items
6 used in Leslie et al. (2011). For the test items, each participant saw only one type of context
7 for a given statement. For the control items, there was only one type of context, which did not
8 vary across conditions.
9

10
11 **Experiment 1: English**

12 *Test items*

13 *Majority characteristic statements*
14

15
16 1. **Background:**

17 a. **neutral**

18 At Stratford's Farm you can enjoy watching thirty of the world's most spectacular
19 butterflies feeding from the wildflower meadow.

20 b. **contradictory**

21 At Stratford's Farm you can learn by watching researchers taking care of thirty mutant
22 butterflies that never develop a means of flying.

23 c. **supportive**

24 At Stratford's Farm you can enjoy watching thirty of the world's most spectacular
25 butterflies flying all around in a tropical environment.

26 **Statement:**

27 Butterflies have wings.
28
29

30
31 2. **Background:**

32 a. **neutral**

33 Cat Rescue takes in and cares for unwanted and abandoned animals. They now look
34 after four cats that can be adopted by responsible owners.

35 b. **contradictory**

36 Cat Rescue takes in and cares for unwanted animals. They now look after four cats who
37 have been in a fight and lost their bristles around the mouth.

38 c. **supportive**

39 Cat Rescue takes in and cares for unwanted and abandoned animals. They now look
40 after four cats, whose long bristles make them really adorable.

41 **Statement:**

42 Cats have whiskers.
43
44

45
46 3. **Background:**

47 a. **neutral**

48 Chester Zoo is home to several African animals, among them five cheetahs. They were
49 shipped from Kenya after detailed health checks.

50 b. **contradictory**

51 Chester Zoo is home to several African animals, among them five cheetahs. They have
52 hurt their legs badly and have been in recovery for months.

53 c. **supportive**

54 Chester Zoo is home to several African animals, among them five cheetahs. They were
55 able to go quicker than two Olympic sprinters in a race.

56 **Statement:**

57 Cheetahs run fast.

4. **Background:**

a. **neutral**

Row Farm is a family farm, where children have the chance to see, meet and take photos of farm animals, including twenty cows.

b. **contradictory**

Row Farm is a family farm, where children have the chance to see the twenty cows which are only fed with corn and other grains.

c. **supportive**

Row Farm is a family farm, where children have the chance to see the twenty cows that roam freely and enjoy the green pastureland.

Statement:

Cows eat grass.

5. **Background:**

a. **neutral**

Shakespeare Tower at the Barbican Estate has many older residents who keep pets. Ten dogs have been acquired recently in the building.

b. **contradictory**

Shakespeare Tower at the Barbican Estate has many older residents who keep pets. Ten dogs have recently gone through cosmetic docking.

c. **supportive**

Shakespeare Tower at the Barbican Estate has many older residents who keep pets. Ten dogs are taken care of, happily moving their flexible appendage.

Statement:

Dogs have tails.

6. **Background:**

a. **neutral**

The Riding Club and Livery Stables in the heart of Wimbledon owns five horses, which are well trained in offering enjoyable rides.

b. **contradictory**

The Riding Club and Livery Stables in the heart of Wimbledon owns five horses, which had accidents and have had hind limbs amputated.

c. **supportive**

The Riding Club and Livery Stables in the heart of Wimbledon owns five horses, which are ready to offer visitors rides on their healthy limbs.

Statement:

Horses have four legs.

7. **Background:**

a. **neutral**

At Trealy Farm visitors can observe and enjoy fifteen rabbits they take care of, which are lucky to have found a safe urban home.

b. **contradictory**

At Trealy Farm visitors can observe fifteen disabled rabbits they take care of, which are lucky to receive treatment for their paralysis.

c. **supportive**

At Trealy Farm visitors can observe and enjoy fifteen rabbits, which have a special way of jumping due to their long and strong back legs.

Statement:

1
2
3 Rabbits hop.
4

5
6 8. **Background:**

7 a. **neutral**

8 Dudley Zoo has three leopards, which are popular with visitors, who are fascinated with
9 their sleek, powerful bodies and their swimming skills.

10 b. **contradictory**

11 Dudley Zoo has three leopards, which are popular with visitors, who are fascinated
12 because they were born without any marks on their bodies.

13 c. **supportive**

14 Dudley Zoo has three leopards, which are popular with visitors, who are fascinated with
15 their full black markings and their rosette pattern.

16 **Statement:**

17 Leopards have spots.
18
19

20
21 9. **Background:**

22 a. **neutral**

23 Residents enjoy the birds that can be found in Central Park. One day, ten sparrows were
24 spotted there, chirping and flying around happily.

25 b. **contradictory**

26 Residents enjoy the birds that can be found in Central Park. One day, ten sparrows got
27 trapped in wires resulting in total separation of their bills.

28 c. **supportive**

29 Residents enjoy the birds that can be found in Central Park. One day, ten sparrows were
30 spotted there, with a bright yellow lower half of the bill.

31 **Statement:**

32 Sparrows have beaks.
33
34

35
36 10. **Background:**

37 a. **neutral**

38 Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose playful games
39 visitors love to watch and photograph.

40 b. **contradictory**

41 Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose fur is all white
42 due to a recessive gene that controls coat color.

43 c. **supportive**

44 Linton Zoo is home to three tigers, Tibor, Baginda and Kaytlin, whose black and orange
45 coats visitors love to photograph.

46 **Statement:**

47 Tigers have stripes.
48
49

50
51 11. **Background:**

52 a. **neutral**

53 The California Sanctuary takes care of five elephants which enjoy year-round access to
54 their beautiful and expansive natural habitat.

55 b. **contradictory**

56 The California Sanctuary takes care of five elephants which have had their elongated
57 nasal part amputated due to crocodile attacks.

58 c. **supportive**
59
60

The California Sanctuary takes care of five elephants which push down trees and pick up straws with their unique elongated nasal part.

Statement:

Elephants have trunks.

12. **Background:**

a. **neutral**

In Battersea Animal Shelter they have four elderly squirrels, which are so tame that they might come and sit on your lap.

b. **contradictory**

In Battersea Animal Shelter they have four elderly toothless squirrels, which do not eat anything with a hard or soft shell.

c. **supportive**

In Battersea Animal Shelter they have four adult squirrels, which run up and down and hold their beloved acorns in their tiny paws.

Statement:

Squirrels eat nuts.

Control items

Definitional statements

1. **Background:**

The New Bennett School is used to film a story on retro pets. To prepare for the visit, they have two farms up and running with 20 ants.

Statement:

Ants are insects.

2. **Background:**

A Greek journalist has taken an interest and compiled a list of Ireland's 50 most eligible bachelors, which will be published online.

Statement:

Bachelors are unmarried.

3. **Background:**

Pets are a wonderful addition to households with children, since they are fun to have around. In a central block of flats, you can find up to ten mice.

Statement:

Mice are animals.

4. **Background:**

The Safari Park hosts many great apes, among them five popular gorillas, who all peel radishes with their teeth before eating them.

Statement:

Gorillas are mammals.

5. **Background:**

The tourism board produced a colored leaflet with details about the fauna and flora of Greenwich Park, which now includes 30 elms.

Statement:

Elms are trees.

Outside the city, it is possible to walk in the woods and explore the rich habitat. One walker spotted 50 mushrooms after a rainy day.
Statement:
Mushrooms are fungi.
7. **Background:**
The RSPCA rehoming process makes sure pets and owners are well matched. More than 30 candidates were considered to adopt ten poodles.
Statement:
Poodles are dogs.
8. **Background:**
Outside the window of a family in Bristol, three robins have built their nest. This is the second year they have used the same spot.
Statement:
Robins are birds.
9. **Background:**
Teachers in Kent engage their pupils in maths lessons using fun and interactive activities to create triangles with threads.
Statement:
Triangles have three sides.
10. **Background:**
Queen Mary's Garden is right in the middle of the city and visitors can enjoy one of the best rose collections in the country for free.
Statement:
Roses are flowers.
11. **Background:**
In the Animal Corner you can learn amazing facts about the twenty cobras they host, which can lift a third of their body off the ground.
Statement:
Cobras are snakes.
12. **Background:**
Soaring temperatures in England have allowed the sea off the Essex coast to warm. A local angler caught fifty anchovies for the first time.
Statement:
Anchovies are fish.

14. **Background:**

The 2012 Summer Olympic Games took place in London, UK from 27 July to 12 August, with an estimated 2000 athletes participating.

Statement:

Athletes are students.

15. **Background:**

Paynes Southdown Bee Farms Limited operate hundreds of hives all along the South Downs area. They are estimated to have over 3000 bees.

Statement:

Bees are worker bees.

16. **Background:**

Blackwell's was the first bookstore in the UK that allowed its customers to purchase books online, with access to 150,000 titles.

Statement:

Books are paperbacks.

17. **Background:**

The Pavillion overlooks the Boating Lake, where you can rent a boat and play with the water. There are currently four swans in the lake.

Statement:

Swans are female.

18. **Background:**

Epping Forest offers numerous activities and events across the year. There are currently ten girls performing at the Open Air Theater.

Statement:

Girls have curly hair.

19. **Background:**

Wildlife officials noticed an increase in calls lately. Ten bears foraging for food were seen in neighborhoods across southern Maine.

Statement:

Bears have white fur.

20. **Background:**

Cape Royds is a rocky promontory overlaid with dirty ice. Over fifty penguins were spotted there, which struggle to cope with global warming.

Statement:

Penguins are male.

21. **Background:**

A new idea is implemented in the Millenium Park that brings together the edible and incredible: veggies, herbs and flowers in one garden.

Statement:

Flowers are yellow.

22. **Background:**

Queens' Park's revitalization plan involved extensive planting and the improvement of the Park entrance. 3000 trees were planted.

Statement:

Trees are deciduous.

23. **Background:**

On Bow Street there are currently twenty cars parked. Many disputes arise over the failure to observe parking 'etiquette'.

Statement:

Cars are black.

24. **Background:**

On Old Kent Road there are thirty houses, which were all built during the last decade. People from ten different nationalities live there.

Statement:

Houses are mansions.

Experiment 2: Greek

Test items

Majority characteristic statements

1. **Background:**

a. **neutral**

Στην φάρμα Κουκάκη μπορείτε να δείτε τριάντα από τις πιο εντυπωσιακές πεταλούδες του κόσμου, που τρέφονται από το λιβάδι με τα αγριολούλουδα.

[English translation: At Koukaki Farm you can see thirty of the world's most spectacular butterflies feeding from the wildflower meadow]

b. **contradictory**

Στην φάρμα Κουκάκη μπορείτε να παρακολουθήσετε ερευνητές να φροντίζουν τριάντα μεταλλαγμένες πεταλούδες, που δεν αναπτύσσουν ποτέ την δυνατότητα να πετάξουν.

[English translation: At Koukaki Farm you can watch researchers taking care of thirty mutant butterflies that never develop a means of flying.]

c. **supportive**

Στην φάρμα Κουκάκη μπορείτε να δείτε και να απολαύσετε τριάντα από τις πιο εντυπωσιακές πεταλούδες του κόσμου να πετάνε γύρω γύρω σε ένα τροπικό περιβάλλον.

[English translation: At Koukaki Farm you can see and enjoy thirty of the world's most spectacular butterflies flying all around in a tropical environment.]

Statement:

Οι πεταλούδες έχουν φτερά.

[English translation: Butterflies have wings.]

2. **Background:**

a. **neutral**

Το σωματείο Σώζω φροντίζει ανεπιθύμητα και εγκαταλελειμμένα ζώα. Τώρα φιλοξενούν τέσσερις γάτες που μπορούν να υιοθετηθούν από υπεύθυνους ιδιοκτήτες.

[English translation: The club 'I save' cares for unwanted and abandoned animals. They now host four cats that can be adopted by responsible owners.]

b. **contradictory**

1
2
3 Το σωματείο Σώζω φροντίζει ανεπιθύμητα ζώα. Τώρα φιλοξενούν τέσσερις γάτες που
4 πήραν μέρος σε έναν καυγά και έχασαν τις τρίχες γύρω από το στόμα τους.

5 [English translation: The club 'I save' cares for unwanted and abandoned animals. They
6 now host four cats who have been in a fight and lost their bristles around the mouth.]

7
8 **c. supportive**

9 Το σωματείο Σώζω φροντίζει ανεπιθύμητα ζώα. Τώρα φιλοξενούν τέσσερις γάτες, που
10 οι καμπυλωτές τρίχες στο πάνω χείλος τους τις κάνουν αξιαγάπητες.

11 [English translation: The club 'I save' cares for unwanted and abandoned animals. They
12 now host four cats, whose curvy bristles around their upper lip make them really
13 adorable.]

14
15 **Statement:**

16 Οι γάτες έχουν μουστάκια.

Definitional statements

1. **Background:**

Το Πρότυπο Σχολείο χρησιμοποιείται για να γυριστεί ένα επεισόδιο για ρετρό κατοικίδια. Για να προετοιμαστούν για το γύρισμα, έφτιαξαν δύο φωλιές μυρμηγκιών.

[English translation: The Model School is used to film an episode on retro pets. To prepare for the visit, they built two farms with ants.]

Statement:

Τα μυρμηγκία είναι έντομα.

[English translation: Ants are insects.]

2. **Background:**

Ένας Έλληνας δημοσιογράφος σκέφτηκε να συλλέξει μία λίστα με τους 50 πιο ελκυστικούς εργένηδες της Ιρλανδίας, που θα δημοσιευτεί στο διαδίκτυο.

[English translation: A Greek journalist thought of compiling a list of Ireland's 50 most eligible bachelors, which will be published on the internet.]

Statement:

Οι εργένηδες είναι ανύπαντροι.

[English translation: Bachelors are unmarried.]

3. **Background:**

Τα κατοικίδια είναι μία υπέροχη προσθήκη σε σπιτικά με παιδιά. Σε μία κεντρική πολυκατοικία, μπορείς να βρεις μέχρι και δέκα ποντίκια, που είναι πολύ ευχάριστη παρέα.

[English translation: Pets are a wonderful addition to households with children. In a central block of flats, you can find up to ten mice, who keep a nice company.]

Statement:

Τα ποντίκια είναι ζώα.

[English translation: Mice are animals.]

4. **Background:**

Το Πάρκο Σαφάρι φιλοξενεί πολλούς μεγάλους πιθήκους, ανάμεσά τους πέντε γορίλες, που ξεφλουδίζουν τα ραπανάκια με τα δόντια τους πριν τα φάνε.

[English translation: The Safari Park hosts many great apes, among them five popular gorillas, who all peel radishes with their teeth before eating them.]

Statement:

Οι γορίλες είναι θηλαστικά.

[English translation: Gorillas are mammals.]

5. **Background:**

Το τουριστικό γραφείο έφτιαξε ένα έγχρωμο φυλλάδιο με λεπτομέρειες σχετικά με την χλωρίδα και την πανίδα του Εθνικού Κήπου που περιλαμβάνει τριάντα πλατάνια.

[English translation: The tourism board produced a colored leaflet with details about the fauna and flora of the National Park, which now includes 30 plane trees.]

Statement:

Τα πλατάνια είναι δέντρα.

[English translation: Plane trees are trees.]

6. **Background:**

Έξω από την πόλη, μπορεί κανείς να περπατήσει στο δάσος και να εξερευνήσει το πλούσιο οικοσύστημα. Ένας περαστικός εντόπισε πενήντα μανιτάρια.

[English translation: Outside the city, it is possible to walk in the woods and explore the rich habitat. One walker spotted 50 mushrooms after a rainy day.]

Statement:

Τα μανιτάρια είναι μύκητες.

[English translation: Mushrooms are fungi.]

7. **Background:**

Το πρόγραμμα της Φιλοζωικής φροντίζει να βρίσκει κατάλληλους ιδιοκτήτες για τα κατοικίδια. Περισσότεροι από 30 υποψήφιοι εξετάστηκαν για να υιοθετήσουν μόλις δέκα κανίς.

[English translation: The Animal Welfare Society's program makes sure to find adequate owners for the pets. More than 30 candidates were considered to adopt ten poodles.]

Statement:

Τα κανίς είναι σκυλιά.

[English translation: Poodles are dogs.]

8. **Background:**

Έξω από το παράθυρο μιας οικογένειας στην Δράμα, τρία χελιδόνια έφτιαξαν την φωλιά τους. Είναι η δεύτερη χρονιά που χρησιμοποιούν το ίδιο σημείο.

[English translation: Outside the window of a family in Drama, three swallows have built their nest. This is the second year they have used the same spot.]

Statement:

Τα χελιδόνια είναι πουλιά.

[English translation: Swallows are birds.]

9. **Background:**

Ο ιππικός Όμιλος Κυκλάδων έχει στο δυναμικό του σαράντα άλογα και προσφέρει μαθήματα σε αρχάριους και προχωρημένους ιππείς.

[English translation: The Cyclades Riding club has forty horses in its force and offers lessons for beginner and advanced riders.]

Statement:

Οι φοράδες είναι άλογα.

[English translation: Female horses are horses.]

10. **Background:**

Το εκτροφείο "ο Παράδεισος" εξειδικεύεται σε ζώα ταϊσμένα στο χέρι. Ανάμεσά τους υπάρχουν τριάντα παπαγάλοι από τροπικές και υποτροπικές χώρες.

[English translation: The breeding group 'The Paradise' specialises in animals fed by hand. Among these, there are thirty parrots from tropical and subtropical countries.]

Statement:

Οι παπαγάλοι είναι πτηνά.

[English translation: Parrots are birds.]

11. **Background:**

Στην Γωνιά του Ζώου μπορείς να μάθεις απίστευτα στοιχεία για τις είκοσι κόμπρες που φιλοξενούν, που μπορούν να σηκώσουν το ένα τρίτο του σώματός τους πάνω από το έδαφος.

[English translation: In the Animal Corner you can learn amazing facts about the twenty cobras they host, which can lift a third of their body off the ground.]

Statement:

Οι κόμπρες είναι φίδια.

[English translation: Cobras are snakes.]

12. **Background:**

Οι υψηλές θερμοκρασίες στην Αγγλία επέτρεψαν στην θάλασσα κοντά στο Έσσεξ να ζεσταθεί. Ένας ντόπιος ψαράς έπιασε πενήντα αντζούγιες για πρώτη φορά.

[English translation: Soaring temperatures in England have allowed the sea off the Essex coast to warm. A local angler caught fifty anchovies for the first time.]

Statement:

Οι αντσούγιες είναι ψάρια.

[English translation: Anchovies are fish.]

*False generalisation statements*13. **Background:**

Explanation	Study	Quantifier	Effect Size	Comment	
1. Quantifier Domain Restriction	Our experiments		majority		
	English	‘all’	-33%	Difference in acceptances between the neutral and the contradictory condition	
	English	‘all the’	-40%		
	English	‘each’	-48%		
Greek	‘oli i’	-19%			
2. Ignorance	Leslie et al. (2011)	‘all’	majority	minority	
			-18%	-21%	Difference in acceptances between exp. 1 and 2a
	Leslie et al. (2011)	‘all’	-1.6%		Paraphrases including subset restriction in exp. 2b
3. Error	Our experiments				
	English	no Q	6.67%	Acceptances of false fillers	
4. Atypical ‘all’	Our experiments	‘all the’	-3%	Acceptances in the neutral condition	
		vs. ‘all’			
		‘each’ vs. ‘all’	-2%		
5. Subkind interpretation	Leslie et al. (2011)	‘all’	-1%	Paraphrases including subtypes in exp. 2b	

¹ See Leslie et al (2011) and discussion in Author (DATE) for consideration of this surprising *increase* in the rates at which statements such as ‘all tigers have stripes’ were accepted as true when the participants performed the knowledge task before evaluating the statements. It is important to note that the knowledge task failed to test whether participants are aware that majority characteristic statements also have exceptions, that is, participants in the knowledge task were not asked to judge whether ‘albino tigers have stripes’ or ‘amputated horses have four legs’, but were only asked to judge false minority characteristic statements such as ‘male ducks lay eggs’.

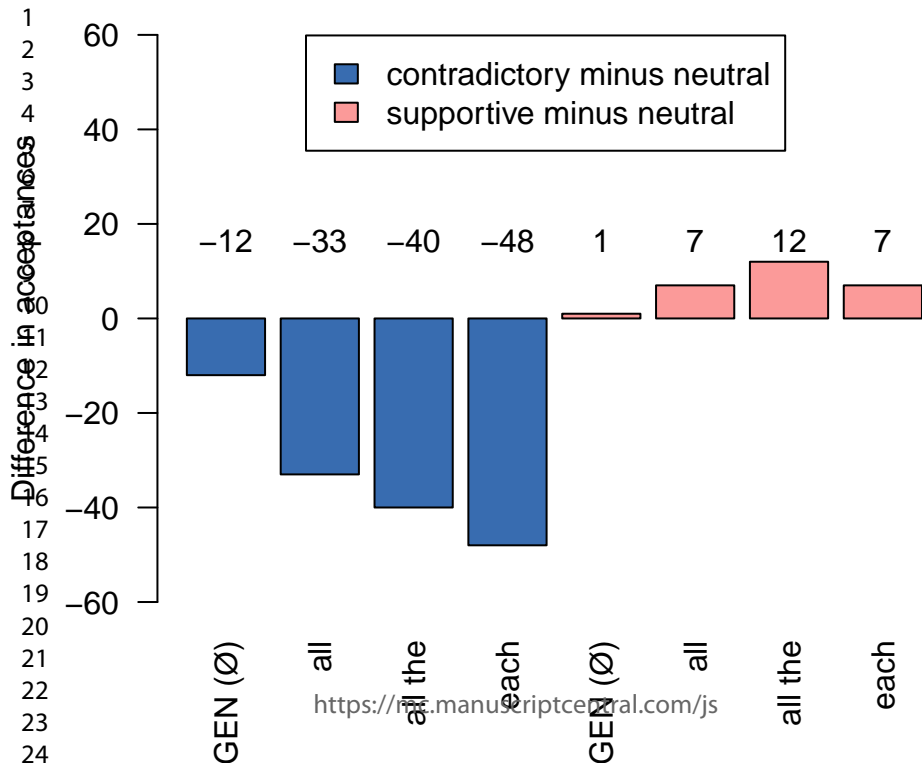

Experiment 1: English

Mean proportion of 'YES' responses

Experiment 1: English

The Relative Effect of Context

Experiment 2: Greek

Mean proportion of 'YES' responses
