@NayAungMD + @Sanghvi_M use Mendelian randomization to demonstrate LDL-chol and trigs may have causal effect on LV remodeling in addition to atherosclerosis.

Acknowledgments

This research has been conducted using the UK Biobank Resource under Application 2964. The authors wish to thank all UK Biobank participants and staff.

1 **Abstract**

2 **Background**

3 Cholesterol and triglycerides are amongst the most well-known risk factors for cardiovascular
4 disease.

5 **Objectives**

6 This study investigates whether higher LDL cholesterol and triglyceride levels, and lower
7 HDL cholesterol are causal risk factors for changes in prognostically-important left
8 ventricular parameters.

9 **Methods**

10 One-sample Mendelian randomization (MR) of 17,311 European individuals from the UK
11 Biobank with paired lipid and CMR data was performed. Two-sample MR was performed
12 using summary level data from the Global Lipid Genetics Consortium (n = 188,577) and UK
13 Biobank CMR sub-study (n = 16,923) for sensitivity analyses.

14 **Results**

15 In one-sample MR analysis, higher LDL cholesterol was causally associated with higher LV
16 end-diastolic volume (b = 1.85 ml, CI = 0.59 to 3.14, p = 0.004) and higher LV mass (b =
17 0.81 g, CI = 0.11 to 1.51, p = 0.023) and triglycerides with higher LV mass (b = 1.37 g, CI =
18 0.45 to 2.3, p = 0.004). HDL cholesterol had no significant association with any LV
19 parameter. Similar results were obtained using two-sample MR. Observational analyses were
20 frequently discordant with those derived from MR.

21 **Conclusions**

22 Mendelian randomization analysis demonstrates that LDL cholesterol and triglycerides are
23 associated with adverse changes in cardiac structure and function, in particular in relation to
24 LV mass. These findings suggest that LDL cholesterol and triglycerides may have a causal
25 effect in influencing cardiac morphology in addition to their established role in
26 atherosclerosis.

27

28 **Condensed abstract**

29 This study investigates whether higher LDL cholesterol and triglyceride levels, and lower
30 HDL cholesterol are causal risk factors for changes in prognostically-important left
31 ventricular parameters. One-sample Mendelian randomization (MR) of 17,311 European
32 individuals from the UK Biobank with paired lipid and CMR data was performed. Two-
33 sample MR was performed using summary level data from the Global Lipid Genetics
34 Consortium (n = 188,577) and UK Biobank CMR sub-study (n = 16,923). Mendelian
35 randomization analysis demonstrates that LDL cholesterol and triglycerides may cause
36 adverse changes in cardiac structure and function, in particular in relation to LV mass.

41 **Abbreviations**

42 CMR = cardiovascular magnetic resonance

43 EDV = end-diastolic volume

44 EF = ejection fraction

45 GRS = genetic risk score

46 HDL = high-density lipoprotein

47 LDL = low-density lipoprotein

48 LV = left ventricle

49 MR = Mendelian randomization

50 MR-PRESSO = Mendelian randomization pleiotropy residual sum and outlier

1 **Introduction**

2 Both the incidence and prevalence of ischemic heart disease, and its long-term
3 sequelae such as heart failure, are on the rise (1, 2). Cardiac imaging is an important and
4 widely-used tool in guiding the diagnosis and treatment of these patients (3). Left ventricular
5 parameters derived from cardiac imaging modalities such as end-diastolic volume, ejection
6 fraction and mass are known to be prognostically important with respect to subsequent major
7 adverse cardiovascular events and cardiovascular death (4, 5). Low-density lipoprotein
8 (LDL) cholesterol is one of the best publicized and most unequivocally implicated risk
9 factors in the development of ischemic heart disease; its causal involvement in atherosclerotic
10 plaque formation in the arterial system is well-elucidated (6). For triglycerides, a causal
11 relationship with cardiovascular disease has also been demonstrated (7) whilst for high-
12 density lipoprotein (HDL) cholesterol, low levels are associated with increased risk of
13 cardiovascular disease but causality has not been established (8). No study, however, has
14 established the causative impact of lipids on the structure and function of the LV.

15 Mendelian randomization (MR) is an analysis methodology whereby genetic variants
16 associated with a proposed risk factor (e.g. raised LDL cholesterol) are utilized as surrogates
17 in order to make causal inferences about the effect of that exposure on an outcome of interest
18 (i.e. left ventricular phenotypes). Given that none of the landmark randomized controlled
19 trials assessing the effect of statins on lipid lowering and cardiovascular outcomes included
20 cardiac imaging in their protocols, examining the association between cholesterol and left
21 ventricular parameters would traditionally be performed via an epidemiological observational
22 study. Through adopting an MR approach, however, typical biases encountered in
23 observational settings such as confounding and reverse causation are mitigated against. With
24 the availability of genotype and cardiovascular magnetic resonance (CMR) data from the UK
25 Biobank as well as large-scale genome wide association studies for lipids (9) and left

1 ventricular phenotypes (10), examining the causal relationship between lipid concentrations
2 and prognostically-important and routinely-measured imaging phenotypes has been made
3 possible.

4 This study investigates whether higher LDL cholesterol and triglycerides and lower
5 HDL cholesterol are causal for changes in left ventricular parameters via individual-level
6 instrumental variable analysis with subsequent sensitivity analysis using summary-level
7 genome-wide association data, in order to gain further understanding of lipids as
8 cardiovascular risk factors.

9 **Methods**

10 **Study cohorts**

11 The UK Biobank is a large population-based prospective cohort study of 500,000
12 individuals aged between 40 to 69 years at the time of initial recruitment between 2006 and
13 2010. It has collected information on health and lifestyle data, physical measurements,
14 biological samples, genotype, and cardiac phenotypes derived from CMR.

15 The overall study protocol has been described in detail previously (11), as has the
16 CMR protocol and reference ranges (12, 13). Genotypes called by the bespoke, closely
17 related UK BiLEVE Axiom and UK Biobank Axiom microarrays (Affymetrix) were imputed
18 using the Haplotype Reference Consortium and merged UK10K and 1000 Genomes phase 3
19 reference panels.

20 Biological samples for biochemical and genetic analysis were taken from participants
21 at their initial baseline visit between 2006 and 2010. CMR examinations, as part of the UK
22 Biobank imaging enhancement, have been performed from 2015 onwards.

23 This study was covered by the general ethical approval for UK Biobank studies from
24 the NHS National Research Ethics Service (17th June 2011 [Ref 11/NW/0382]; extended on
25 10th May 2016 [Ref 16/NW/0274]).

1 **Lipid measurements**

2 Direct LDL cholesterol serum concentration was measured by enzymatic protective
3 selection analysis on a Beckman Coulter AU5800 clinical chemistry analyzer (Beckman
4 Coulter, Brea, California, USA). For participants where direct measurements were missing,
5 LDL cholesterol concentration was derived using the Friedewald calculation as long as serum
6 triglyceride concentration was ≤ 155 mg/dL (4 mmol/L) (14). Where participants had
7 indicated they used lipid-lowering medications (UK Biobank field ID 20003), LDL
8 cholesterol values were multiplied by a factor of 1.43 in order to estimate untreated LDL
9 cholesterol serum concentration (15).

10 Serum HDL cholesterol concentration was measured by the enzyme immune-
11 inhibition method and serum triglyceride concentration was measured using a series of
12 coupled enzymatic reactions, both on a Beckman Coulter AU5800 clinical chemistry
13 analyzer (Beckman Coulter).

14 **Variant selection and genetic risk score construction**

15 A weighted genetic risk score (GRS) for LDL cholesterol was built by using variants
16 associated with LDL cholesterol attaining genome-wide significance ($p < 5 \times 10^{-8}$) reported in
17 the data from the Global Lipids Genetic Consortium (GLGC) (9). Following linkage
18 disequilibrium clumping (at $r^2 < 0.01$), 101 independent variants were included in the GRS.
19 Equivalent processes were performed in the same dataset for HDL cholesterol and
20 triglycerides yielding 125 and 73 variants, respectively (Supplementary Tables 1–3). The
21 weighted GRS was calculated for each UK Biobank participant of European ancestry by
22 summing the product of the effect sizes and the number of effect alleles across all selected
23 variants. Variance explained by the weighted GRS was calculated by regressing the measured
24 lipid values on their corresponding GRS. Correlation between the lipid genetic risk scores
25 was assessed by Pearson's test.

1 **Statistical analysis**

2 *Baseline data and observational analysis*

3 Baseline data is presented in categorized fashion with participants grouped into
4 unequal bins based on their serum LDL cholesterol percentile. To examine trend across the
5 groups, Cuzick's extension of the Wilcoxon rank sum test was used for continuous variables
6 whilst the chi-squared test for trend was used for ordinal variables. CMR parameters used as
7 dependent variables were LV end-diastolic volume (LVEDV), LV mass and LV ejection
8 fraction (LVEF). Non-European ancestries were excluded in order to improve homogeneity
9 of the study population and align with the genetic analyses.

10 To observationally examine the association between phenotypic lipid concentration
11 on important LV parameters, multivariable linear regression models were fitted for each
12 dependent variable. Co-variables included age at recruitment, sex, log-transformed body mass
13 index (BMI), body surface area (BSA, calculated via Dubois and Dubois equation), systolic
14 blood pressure adjusted for anti-hypertensive medication use (by adding 15mmHg) (16),
15 physical activity as determined by log-transformed total metabolic equivalent of task (MET)
16 minutes per week, smoking status, log-transformed glycated hemoglobin (HbA1c) and
17 presence of cardiovascular disease (defined as participants diagnosed or reporting myocardial
18 infarction, angina, heart failure, arrhythmias [including atrial fibrillation], cardiomyopathy,
19 stroke or peripheral vascular disease).

20 *Instrumental variable analysis*

21 MR was performed using the two-stage least squares method (one-sample MR) as
22 implemented in the R package "ivpack". We included age, sex, BSA and the first five genetic
23 principal components as covariates. Data are presented as the change in LV phenotype per 39
24 mg/dL (1 mmol/L) increment in lifetime LDL cholesterol and HDL cholesterol exposure and
25 per 89 mg/dL (1 mmol/L) in lifetime triglyceride exposure. Significant causal associations

1 between each lipid GRS and the LV phenotype were additionally tested for the presence of an
2 *independent* effect by including all three lipid genetic risk scores in the regression model. We
3 assessed the presence of weak instrument bias (also known as violation of *relevance*
4 assumption in MR) by calculating the F-statistic from the linear regression between GRS and
5 LV phenotype. The Durbin-Wu-Hausman test of regressor endogeneity was performed to
6 assess the consistency of the estimate of LV parameter change provided by the instrumental
7 variable analysis compared to the observational analysis. Statistical power of instrumental
8 variable analysis was estimated according to the method proposed by Brion (17). At our
9 available sample size of ~17,000 individuals, our one-sample MR analyses were powered at
10 80% ($\alpha=0.05$) to detect the minimum effect sizes of 0.39 to 0.53 ml for LVEDV, 0.16
11 to 0.24% for LVEF and 0.31 to 0.45 g for LV mass (Supplementary Figure 1).

12 *Sensitivity analyses*

13 As sensitivity analysis to examine the potential causal relationship between serum
14 lipids and prognostically-important LV parameters, two-sample MR with summary-level
15 genome-wide association data from the GLGC ($n = 188,577$) (9) and UK Biobank CMR sub-
16 study ($n = 16,923$) (10) was performed. An MR effect estimate for each LV parameter was
17 calculated by the inverse variance-weighted method with robust penalized regression to
18 minimize the influence of genetic variants with outlying ratio estimates (18). Two-sample
19 MR effect sizes are presented as the change in LV parameter per one standard deviation
20 increase in LDL cholesterol (34 mg/dL [0.87 mmol/L]), HDL cholesterol (15 mg/dL [0.38
21 mmol/L]) and triglycerides (90 mg/dL [1.02 mmol/L]) respectively.

22 Additionally, we used the robust penalized MR-Egger, weighted median and
23 weighted mode methods to evaluate the validity of genetic instruments (18, 19). We assessed
24 the presence of directional horizontal pleiotropy by conducting the MR-Egger intercept test
25 for which a p value <0.1 was considered as evidence of pleiotropic bias (20). We also

1 conducted the MR pleiotropy residual sum and outlier (MR-PRESSO) for further evaluation
2 of horizontal pleiotropy. This test applies three procedures: (i) detection of horizontal
3 pleiotropy with the global test; (ii) correction for horizontal pleiotropy by outlier removal
4 known as the outlier test; and (iii) assessing significant differences in the causal estimates
5 before and after correction for outliers using the distortion test. Additionally, we conducted
6 multivariable MR in order to establish the potential causal effect on LV parameters
7 independent of the effects of the other lipid fractions (21).

8 As further sensitivity analysis, we performed one-sample MR following additional
9 adjustment for all co-variables (age at recruitment, sex, BMI, BSA, systolic blood pressure
10 adjusted for anti-hypertensive medication use, physical activity, smoking status, HbA1c and
11 presence of cardiovascular disease). We built models examining the association between lipid
12 parameters and LV phenotypes using both phenotypic and genetically-determined lipid levels
13 as co-variables to examine any attenuation effect. We also interrogated the GWAS Catalog
14 database to identify the variants included in the lipid GRSs which were associated with other
15 lipid and non-lipid traits at a genome-wide significance level. We manually examined this list
16 and excluded the variants associated with traits (e.g. cardiovascular disease, cardiovascular
17 risk factors) which might influence LV remodeling (Appendix 1) and performed the analysis
18 using a restricted GRS.

19 We investigated the direction of causality by the MR-Steiger test which is based on
20 the absolute correlations of the genetic variants with the exposure and outcome. The two-
21 sample MR analyses were conducted using the “MendelianRandomization” and
22 “TwoSampleMR” R packages.

23 *Statin effect*

24 To examine whether statin use modified the relationship of phenotypic (measured)
25 LDL cholesterol and the LDL GRS, interaction analysis was performed using “statin use x

1 standardized genetic risk score” as an interaction term. For this analysis, we used the LDL
2 cholesterol measurements unadjusted for statin use. We also investigated the effect
3 modification by statin therapy on the association between the LDL GRS and LV parameters.

4 The causal effects were considered significant only if supported by both one-sample
5 and two-sample MR analyses at $p < 0.05$. All analyses were conducted in the R (3.6.0)
6 statistical computing environment.

7 **Results**

8 Demographic and clinical characteristics of study participants, as well as median
9 CMR parameter values, are outlined in Table 1. There were 436,064 individuals for whom
10 cholesterol data was available; of these, 17,311 had CMR examinations. Individuals in the
11 top decile for phenotypic LDL cholesterol were older, predominantly female and had higher
12 BMI, blood pressure and HbA1c measurements. The variances in lipid measurements
13 explained by the corresponding genetic risk scores were 10.8% (F-statistic = 2492), 7.3% (F-
14 statistic = 1811), and 5.0% (F-statistic = 925) for LDL cholesterol, HDL cholesterol and
15 triglycerides, respectively. Large F-statistic values (>10) indicated that the MR analyses were
16 unlikely to be affected by the weak instrument bias. The strength of correlations between
17 lipid genetic risk scores was low (Pearson’s r 0.1 to -0.26, $p > 0.1$, Supplementary Figure 2).

18 **LDL cholesterol**

19 In observational analysis (Table 2, Figure 1/Central Illustration), a 39 mg/dL (1
20 mmol/L) increase in LDL cholesterol levels were associated with lower LVEDV ($b = -2.44$
21 ml, confidence interval [CI] = -2.91 to -1.97, $p < 0.0001$), lower LV mass ($b = -0.64$ g, CI = -
22 0.9 to -0.38, $p < 0.0001$) and higher LVEF ($b = 0.13\%$, CI = 0.01 to 0.24, $p = 0.03$). In
23 contrast, in one-sample MR analysis, a 39 mg/dL (1 mmol/L) increase in lifetime LDL
24 cholesterol exposure was associated with higher LVEDV ($b = 1.85$ ml, CI = 0.59 to 3.14, $p =$
25 0.004), higher LV mass ($b = 0.81$ g, CI = 0.11 to 1.51, $p = 0.023$); there was no significant
26 change in ejection fraction. Analyses controlling for HDL and triglycerides genetic

1 instruments did not change the significant results (Supplementary Table 4) indicating that the
2 causal relationships between LDL cholesterol and LVEDV and LV mass were robust to
3 confounding from other lipid fractions. One sample-MR was additionally performed
4 following adjustment for all co-variates and yielded similar results (these are detailed, along
5 with results for HDL and triglycerides, in Supplementary Table 5). Models examining the
6 association between LV parameters and genetically determined lipid levels where phenotypic
7 lipid levels were included as a co-variate demonstrated no significant attenuation of these
8 associations indicating an independent effect (Supplementary Table 6). Sensitivity analysis
9 performed using a restricted list of variants in the GRS following exclusion of potentially
10 pleiotropic variants (69, 81 and 50 variants remained for LDL, HDL and triglycerides,
11 respectively) yielded concordant results to the primary analysis (Supplementary Table 7).

12 In sensitivity analysis using two-sample MR (Table 3, Figure 1/Central Illustration),
13 concordant associations were noted for LVEDV (inverse-variance weighted [IVW] $b = 1.62$
14 ml, CI 0.32 to 2.91, $p = 0.014$) and LV mass (IVW $b = 0.66$ g, CI 0.1 to 1.22, $p = 0.021$).
15 Again, there was no association demonstrated for LVEF. These results were also confirmed
16 using multivariable MR (Supplementary Table 8). Based on Egger intercept p-values, no
17 directional horizontal pleiotropy was detected. Sensitivity analyses by MR-Egger, weighted
18 median and weighted mode methods produced associations with concordant effect directions
19 although the confidence intervals were much wider, as expected (Supplementary Table 9 and
20 Supplementary Figure 3). The MR-PRESSO method found evidence of horizontal pleiotropy
21 for the association between LDL cholesterol and LVEDV but upon removal of outlier
22 variants, the effect estimates were not significantly changed as per the distortion tests
23 (Supplementary Table 10). The MR-Steiger test suggested that the assumption of causal
24 directionality for the relationships between the LDL GRS and the LV parameters was correct
25 (Supplementary Table 11).

1 **HDL cholesterol**

2 In multivariate analysis, higher phenotypic HDL cholesterol levels were associated
3 with higher LVEDV ($b = 8.27$ ml, CI = 7 to 9.53, $p < 0.0001$) and higher LV mass ($b = 1.34$
4 g, CI = 0.64 to 2.04, $p = 0.0002$) with no association with LVEF. Associations demonstrated
5 in observational analysis were not borne out in one-sample MR analysis with no association
6 demonstrated between genetically higher lifetime exposure to HDL cholesterol and changes
7 in LVEDV, LVEF or LV mass. This was further demonstrated using summary data in two-
8 sample MR (Table 3, Figure 1/Central Illustration). These results were reproduced in
9 sensitivity analyses with MR-Egger, weighted median and weighted mode methods
10 (Supplementary Table 9 and Supplementary Figure 4).

11 **Triglycerides**

12 Examining the effect of triglycerides on CMR parameters, observational analysis
13 indicated that an 89 mg/dL (1 mmol/L) increase in triglyceride concentration was associated
14 with lower LVEDV ($b = -3.98$ ml, CI = -4.4 to -3.55, $p < 0.0001$), higher LVEF ($b = 0.12\%$,
15 CI = 0.02 to 0.22, $p = 0.024$) and lower LV mass ($b = -0.65$ g, CI = -0.89 to -0.42, $p =$
16 < 0.0001). One-sample MR analysis demonstrated that there was no association with changes
17 in LVEDV but an 89 mg/dL (1 mmol/L) increase in lifetime triglyceride exposure yielded a
18 reduction in LVEF ($b = -0.52\%$, CI = -0.92 to -0.13, $p = 0.011$) and higher LV mass ($b = 1.37$
19 g, CI = 0.45 to 2.3, $p = 0.004$). Additional adjustment for HDL and triglycerides genetic
20 instruments produced similar results (Supplementary Table 4). Sensitivity analysis performed
21 using a restricted list of variants in the GRS following exclusion of potentially pleiotropic
22 variants yielded concordant results to the primary analysis (Supplementary Table 7).

23 Two-sample MR sensitivity analysis demonstrated no significant association between
24 triglyceride concentration and LVEDV or LVEF; it showed concordant results for LV mass
25 (IVW $b = 0.61$ g, CI 0.04 to 1.18, $p = 0.036$). Similar results were observed in multivariable

1 MR analysis (Supplementary Table 8). There was evidence of horizontal pleiotropy for the
2 association between triglycerides and LVEDV but removal of the outlier variants did not
3 significantly change the effect estimates as indicated by the distortion tests (Supplementary
4 Table 10) . Sensitivity analysis examining the association of triglycerides and LV mass using
5 MR-Egger, weighted median and weighted mode methods did not reach significance due to
6 wider confidence interval although they showed concordant effect directions (Supplementary
7 Table 9 and Supplementary Figure 5). The assessment of causal directionality using the MR
8 Steiger test supported what this study’s hypothesis has proposed (Supplementary Table 11).

9 **Statin usage**

10 To ascertain the effect of statin usage, the relationship between measured
11 (phenotypic) LDL cholesterol and the standardized genetic risk score for LDL cholesterol
12 was examined based on whether an individual was a statin user or not. Statin use significantly
13 modified (p for interaction <0.0001) the relationship between measured (phenotypic) LDL
14 cholesterol and the standardized genetic risk score for LDL cholesterol with statin users
15 exhibiting a reduced measured LDL cholesterol for a given degree of genetic risk (Figure
16 2A). As demonstrated in Figure 2B, as genetic risk score percentile group increases, the
17 relative increase in measured LDL cholesterol is greater in each group in non-statin users,
18 compared to statin users. Examination of the effect modification of statin therapy on the
19 relationships between genetically determined LDL and LV parameters did not yield any
20 significant results (Supplementary Table 12).

21 **Discussion**

22 This study is the first to conduct MR analyses to examine the effect of lipids in the
23 development of changes in prognostically-important LV parameters. Using instrumental
24 variable analysis in 17,311 individuals with paired genotype and CMR data with subsequent
25 sensitivity analysis using summary-level data, we demonstrate an association between

1 increased LDL cholesterol and higher LVEDV and LV mass, triglycerides with higher LV
2 mass whilst HDL cholesterol does not result in any significant alterations in LV structure and
3 function. Importantly, results derived from observational analysis were frequently discordant
4 from those obtained via MR.

5 **Lipids as a risk factor: beyond atherosclerosis**

6 The substantial body of evidence indicating a continuous, positive and graded
7 relationship between LDL cholesterol and cardiovascular mortality make cholesterol
8 measurement and prescription of lipid-lowering therapy a cornerstone of primary and
9 secondary prevention in cardiovascular disease (22). Left ventricular remodeling is a clinical
10 characterization of the development and progression of morphological changes in the LV that
11 result in ventricular dysfunction (23). These morphological changes have been shown to
12 occur in association with exposure to other important risk factors, such as hypertension (24)
13 or raised body mass index (25), and are frequently subclinical – present prior to any discrete
14 clinical event.

15 In this study, MR analysis demonstrates that both LDL cholesterol and triglycerides
16 have a potentially causal association with increased LV mass. The importance of LV mass as
17 a biomarker in cardiovascular disease is demonstrated in studies where therapeutic
18 interventions that result in a reduction in LV mass have decreased the number of
19 cardiovascular events (26). Importantly, raised LV mass has also been shown to increase the
20 risk of incident heart failure even in patients free of known ischemic heart disease or previous
21 myocardial infarction – conditions which are atherosclerosis-driven (27). With LDL
22 cholesterol and triglycerides appearing to be causative of myocardial remodeling by
23 increasing LV mass, it suggests that they influence the development of cardiovascular disease
24 not only by atherosclerosis but also by causing adverse alterations in cardiac structure and
25 function.

1 An insight into the potential mechanistic pathways by which lipids might generate
2 these alterations can be gleaned from work examining the pleiotropic effects of statins on the
3 mevalonate pathway. The mevalonate pathway is an ubiquitous, negative feedback-controlled
4 pathway responsible for cholesterol synthesis; statins act to inhibit cholesterol synthesis by
5 preventing conversion of HMG-CoA to mevalonate. However, since mevalonate is not the
6 immediate precursor of cholesterol and also acts as a precursor for several other molecules,
7 its inhibition leads to pleiotropic effects being observed, particularly through inhibition of
8 synthesis of isoprenoid intermediates of the mevalonate pathway such as
9 farnesylpyrophosphate and geranylgeranylphosphate. An important function of these
10 isoprenoids is the post-translational modification of many GTP-binding proteins of the Rho
11 family (28) of signaling proteins. Rho proteins have been shown to mediate the development
12 of cardiac hypertrophy via a number of mechanisms (29). For example, RhoA is involved in
13 formation of actin stress fibers and focal adhesion complexes through Rho kinase activation
14 and myosin light chain phosphorylation (30). Rac1 and Cdc42 regulate actin cytoskeletal
15 processes called lamellipodia and filopodia, which are thought to contribute to morphological
16 changes associated with LV hypertrophy (31, 32). Additionally, Rho proteins may regulate
17 the hypertrophic process by activating downstream signaling molecules such as mitogen-
18 activated protein (MAP) kinases (33). Additional work examining non-hypercholesterolemic
19 transgenic rabbit models of hypertrophic cardiomyopathy demonstrated that simvastatin
20 administration was associated with regression of cardiac hypertrophy and improvement of
21 LV filling pressures (34). If lipid-lowering therapy has been shown to alter cardiac
22 phenotypes, it is possible that the reverse effect may be true with increased cholesterol
23 exposure.

24 A further aspect of this study is heightening the importance of raised serum
25 triglycerides as a cardiovascular risk factor. Despite previous contention, triglycerides have

1 emerged as a recognized causal risk factor (7). Current American guidelines recommend
2 intervention when triglycerides are >150 mg/dL (>1.7 mmol/L) (35) and European guidelines
3 recommend the use of pharmacotherapy when triglycerides are >200 mg/dL (2.3 mmol/L) in
4 high risk patients and when lifestyle measures have failed (36). By way of illustration, 40%
5 of our cohort had a serum triglyceride measurement >150 mg/dL (1.7 mmol/L). Along with
6 the recent data published by the REDUCE-IT investigators (37, 38), this study provides
7 further evidence of the importance of triglycerides as a cardiovascular risk factor and perhaps
8 will help in establishing a role for triglyceride reduction in a broader group of patients. In
9 contrast, our findings of a lack of association with any LV remodeling parameter agree with
10 the current narrative of HDL cholesterol not being associated with cardiovascular outcomes.

11 **Observational analysis vs MR**

12 A particularly interesting feature of this study is the discordance between the results
13 produced from observational analysis compared to those derived from a MR approach. As
14 examples, after adjusting for potential confounders, LDL cholesterol was shown to be
15 observationally associated with significantly lower end-diastolic volume and LV mass.
16 However, the directionality of association was reversed in one-sample and two-sample MR.
17 Moreover, observationally HDL cholesterol was associated with higher end-diastolic volume
18 and mass whereas no significant association was demonstrated using MR. The MR approach
19 has gained much traction due its ability to permit experimental analysis free from the biases
20 common to observational approaches. The results outlined above are tacit in highlighting the
21 limitations of observational methods. Of particular note are the observational results for LDL
22 cholesterol which *prima facie* suggest higher serum concentrations to be associated with
23 ameliorative changes in the LV. This is in contrast to previous cross-sectional studies which
24 have suggested adverse remodeling changes in association with non-HDL cholesterol and
25 total cholesterol, respectively (39, 40). That this study, particularly with its large sample size

1 (n = 17,311), would deliver contrasting results in terms of both the previous literature and
2 biological expectation is surprising. However, it may be instructive in characterizing a further
3 challenge as biobank-based research becomes more common. As the degree of phenotyping
4 undertaken by biobanks becomes more extensive, the temporal gap between different
5 assessments will grow. For example, in this study, biochemistry samples for lipid
6 quantification were drawn between 2006 and 2010 whereas CMR examinations have taken
7 place since 2015. The observational analysis, therefore, is not strictly cross-sectional and it is
8 possible that the LDL cholesterol results were confounded by modulating factors which
9 occurred between the two time points. One particular and relevant confounding intervention
10 would be the introduction/continuation of statin therapy during the period before CMR
11 examination. Whilst it was reassuring that examination of the relationship of measured LDL
12 and genetically-determined LDL demonstrated that statin use was consistently associated
13 with relatively lower phenotypic LDL across the genetic LDL risk score range, a natural
14 extension of this study would have been to investigate whether statins conferred any
15 beneficial effect on LV parameters. Our examination of the effect modification by statin
16 therapy on the association between the LDL GRS and LV parameters did not yield any
17 significant results. However, a significant limitation is that data regarding commencement,
18 duration, dosage and dosage change of pharmacological therapy (statins included) is not
19 available in the UK Biobank.

20 **Strengths and limitations**

21 There are a number of strengths to this work, the first to investigate the potentially
22 causal relationship between routinely measured lipid fractions and prognostically-important
23 LV parameters. Firstly, the effect estimates for building the genetic risk scores for LDL
24 cholesterol, HDL cholesterol and triglycerides were taken from an independent dataset
25 (GLGC) which is one of the largest of its kind and has helped avoid circular inferences or

1 overestimation in our results. Secondly, this study has sufficient sample size as confirmed by
2 power calculations performed *a priori* to its commencement. Finally, both one-sample and
3 two-sample MR have been performed, providing an additional level of confidence
4 concerning the results provided.

5 In addition to the lack of pharmacotherapy data explained above, whilst supporting
6 data providing mechanistic insights has been outlined, this study is unable to determine the
7 specific molecular mechanism(s) for the potentially causal relationship between LDL
8 cholesterol and triglycerides and alterations in LV parameters, although it is hoped that the
9 findings presented may prompt further basic science investigations. Additional limitations
10 mostly pertain to the MR technique. It is acknowledged that MR assumptions of
11 independence and exclusion restriction cannot be fully tested nor can residual horizontal
12 pleiotropy be fully ruled out. However, as described, the MR-Egger intercepts did not deviate
13 significantly from the origin. Bidirectional MR was not performed to determine whether LV
14 genetic risk scores are causally associated with alterations in lipid measurements; this was
15 because of the limited number of significant genome-wide variants for LV parameters.
16 Nevertheless, MR-Steiger results suggested that assumptions of causal directionality were
17 accurate. Finally, our study was restricted to Europeans because of the limited number of
18 non-European participants in our CMR data. Thus, the insights gained cannot be extended to
19 other ancestries. This limitation is likely be overcome in the near future by the ongoing UK
20 Biobank CMR study with a target sample size of 100,000, as well as through collaboration
21 with other maturing national biobanks, which will increase available data for other
22 ethnicities.

23 **Conclusion**

24 By performing Mendelian randomization this study has investigated the association
25 between lipids and CMR parameters. It provides evidence that exposure to higher levels of

1 LDL cholesterol and triglycerides are associated with changes in the left ventricle known to
2 portend adverse prognosis. It improves our understanding of serum lipids as a risk factor for
3 cardiovascular disease by demonstrating evidence of direct impact on cardiac structure and
4 function.

5

6

1 **Perspectives**

2 Competency in medical knowledge 1: Mendelian randomization can be used as an approach
3 to infer causation in situations where randomized control trials are unable to be performed.

4 Competency in medical knowledge 2: Mendelian randomization can overcome biases
5 observed in observational studies. This is highlighted in this study where observational data
6 and MR data for LDL cholesterol show discordant effects on LV phenotypes.

7 Translational Outlook 1: The role of lipids as a cardiovascular risk factor may extend further
8 than their effects on atherogenesis to directly impact prognostically-important LV
9 phenotypes.

Figures

Figure 1 (Central Illustration):

Title: Change in LV parameter by lipid fraction in observational, one-sample MR and two-sample MR analysis.

Caption: There is a potentially causal association between increased LDL-cholesterol and higher LV end-diastolic volume and LV mass, and triglycerides with higher LV mass whilst HDL cholesterol does not result in any significant alterations in LV structure and function. Observational data is presented as change in LV parameter per 39 mg/dL (1 mmol/L) in LDL and HDL cholesterol and 89 mg/dL in triglycerides. One-sample Mendelian randomization (MR) data is presented as change in LV parameter per 39 mg/dL (1 mmol/L) for LDL and HDL cholesterol and 89 mg/dL for triglyceride increase in lifetime lipid parameter exposure. For two-sample MR, data is presented as the change in LV parameter per one standard deviation increase in LDL cholesterol (34 mg/dL [0.87 mmol/L]), HDL cholesterol (15 mg/dL [0.38 mmol/L]) and triglycerides (90 mg/dL [1.02 mmol/L]) respectively.

Figure 2:

Title: Relationship between genetic risk score for LDL cholesterol and phenotypic LDL cholesterol by statin usage.

Caption: Figure 2A: Statin use significantly modifies (p for interaction <0.0001) the relationship between measured (phenotypic) LDL cholesterol and the standardized genetic risk score for LDL cholesterol with statin users exhibiting a reduced measured LDL cholesterol for a given degree of genetic risk.

Figure 2B: As genetic risk score percentile group increases, the relative increase in measured LDL cholesterol is greater in each group in non-statin users, compared to statin users.

Table 1: Demographic data

Variable	Percentile group by serum LDL cholesterol concentration					P-value for trend
	0% - 50%	51% - 75%	76% - 90%	91% - 95%	96% - 100%	
n	215845	109763	66350	22204	21902	
LDL cholesterol* (mg/dL)	115 (20)	146 (19)	165 (22)	181 (25)	200 (33)	<0.001

Table 2: Effect of phenotypic and genetically-determined lipid levels on LV parameters

Lipid parameter	Phenotype	Observational effect size	Observational 95% CI	Observational p-value	MR effect size	MR 95% CI	MR p-value	Durbin-Wu-Hausman p-value	F-statistic
	LV EDV (ml)	-2.44	-2.91 to -1.97	<0.0001	1.85	0.59 to 3.14	0.004	<0.0001	2492.0
LDL Cholesterol	LV EF (%)	0.13	0.01 to 0.24	0.03	0.04	-0.26 to 0.34	0.8	0.22	2492.0
	LV mass (g)	-0.64	-0.90 to -0.38	<0.0001	0.81	0.11 to 1.51	0.023	0.0005	2492.0
	LV EDV (ml)	8.27	7.0 to 9.53	<0.0001	3.48	-0.15 to 7.08	0.056	<0.0001	1811.2
HDL Cholesterol	LV EF (%)	0.04	-0.27 to 0.35	0.806	0.43	-0.43 to 1.3	0.312	0.403	1811.2
	LV mass (g)	1.34	0.64 to 2.04	0.0002	0.11	-1.91 to 2.13	0.914	0.076	1811.2
	LV EDV (ml)	-3.98	-4.4 to -3.55	<0.0001	-0.54	-2.17 to 1.12	0.517	<0.0001	925.1
Triglycerides	LV EF (%)	0.12	0.02 to 0.22	0.024	-0.52	-0.92 to -0.13	0.011	0.0003	925.1
	LV mass (g)	-0.65	-0.89 to -0.42	<0.0001	1.37	0.45 to 2.3	0.004	0.0002	925.1

Observational data is adjusted for age at recruitment, sex, BMI, BSA, systolic blood pressure adjusted for anti-hypertensive medication use, physical activity, smoking status, HbA1c and presence of cardiovascular disease; data is presented for change in LV parameter per 39 mg/dL (1 mmol/L) in LDL and HDL cholesterol and 89 mg/dL in triglycerides.

One-sample Mendelian randomization (MR) data is adjusted for age, sex, BSA and the first five principal components and data is presented as change in LV parameter per 39 mg/dL (1 mmol/L) for LDL and HDL cholesterol and 89 mg/dL for triglyceride increase in lifetime lipid parameter exposure

Table 3: Two-sample Mendelian randomization analysis using summary level data

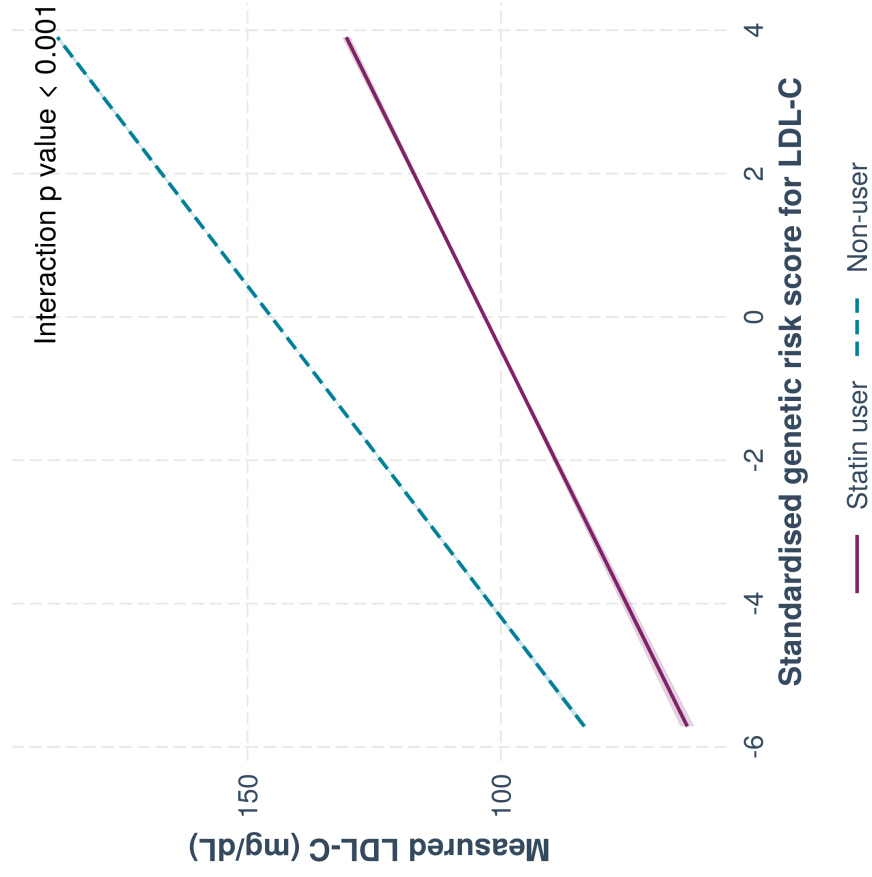

Lipid parameter	Phenotype	IVW effect size	IVW confidence interval	IVW p-value	Egger intercept	Egger intercept p-value
	LV EDV (ml)	1.62	0.32 to 2.91	0.014	-0.023	0.655
LDL Cholesterol	LV EF (%)	0.04	-0.17 to 0.25	0.705	-0.007	0.490
	LV mass (g)	0.66	0.1 to 1.22	0.021	0.024	0.368
	LV EDV (ml)	1.16	-0.07 to 2.39	0.065	0.013	0.820
HDL Cholesterol	LV EF (%)	0.18	-0.08 to 0.44	0.184	-0.003	0.812
	LV mass (g)	0.32	-0.26 to 0.89	0.279	-0.029	0.296
	LV EDV (ml)	-0.43	-1.73 to 0.86	0.512	-0.039	0.504
Triglycerides	LV EF (%)	-0.30	-0.66 to 0.06	0.106	-0.002	0.889
	LV mass (g)	0.61	0.04 to 1.18	0.036	0.034	0.188

For two-sample MR the change in LV parameter reflects an increase per 34 mg/dL (0.87 mmol/L) 15 mg/dL (0.38 mmol/L) and 90 mg/dL (1.02 mmol/L) increase in LDL cholesterol, HDL cholesterol and triglycerides, respectively.

Mendelian randomization analysis demonstrates a potentially causal association between increased LDL-cholesterol and higher LV end-diastolic volume and LV mass, and triglycerides with higher LV mass.

Supplementary Table 4. One-sample MR with a single instrument and additional adjustment for all three lipid instruments

Lipid parameter	Phenotype	Single instrument MR effect size	Single instrument MR 95% CI	Single instrument MR p-value	Multiple instrument MR effect size	Multiple instrument MR 95% CI	Multiple instrument MR p-value
LDL Cholesterol	LV EDV (ml)	1.85	0.59 to 3.14	0.004	2.12	0.08 to 3.46	0.001
	LV mass (g)	0.81	0.11 to 1.51	0.023	0.77	0.04 to 1.51	0.037
Triglycerides	LV EF (%)	-0.52	-0.92 to -0.13	0.011	-0.54	-0.99 to -0.10	0.019
	LV mass (g)	1.37	0.45 to 2.3	0.004	1.54	0.50 to 2.59	0.004

Supplementary Table 5. One-sample MR adjusted for all potential confounders

Lipid parameter	CMR parameter	MR effect size	MR 95% CI	MR p-value
LDL Cholesterol	LV EDV (ml)	1.68	0.38 to 3.0	0.010
	LV EF (%)	0.06	-0.25 to 0.37	0.710
	LV mass (g)	0.72	0.01 to 1.45	0.046
HDL Cholesterol	LV EDV (ml)	3.41	-0.35 to 7.16	0.071
	LV EF (%)	0.44	-0.47 to 1.35	0.338
	LV mass (g)	0.40	-1.68 to 2.49	0.703
Triglycerides	LV EDV (ml)	-0.93	-2.62 to 0.78	0.279
	LV EF (%)	-0.56	-0.98 to -0.15	0.008
	LV mass (g)	1.04	0.1 to 1.99	0.034

One-sample MR data following additional adjustment for age at recruitment, sex, BMI, BSA, systolic blood pressure adjusted for anti-hypertensive medication use, physical activity, smoking status, HbA1c and presence of cardiovascular disease; data is presented for change in LV parameter per 1 mmol/L increase in lifetime exposure to lipid parameter

Supplementary Table 6: Associations between LV parameters and lipid parameter with phenotypic and genetically-determined lipid level included as covariates

Phenotype	Lipid parameter	Effect size	95% CI	p-value
LV EDV	Measured LDL cholesterol	-3.91	-4.39 to -3.44	1.60E-58
LV EDV	Genetically-determined LDL cholesterol	5.91	4.54 to 7.29	3.63E-17
LV EF	Measured LDL cholesterol	0.24	0.12 to 0.35	4.18E-05
LV EF	Genetically-determined LDL cholesterol	-0.20	-0.53 to 0.12	2.24E-01
LV mass	Measured LDL cholesterol	-0.52	-0.79 to -0.26	1.11E-04
LV mass	Genetically-determined LDL cholesterol	1.36	0.60 to 2.13	5.00E-04
LV EDV	Measured HDL cholesterol	12.26	11.02 to 13.50	4.30E-83
LV EDV	Genetically-determined HDL cholesterol	-8.96	-12.82 to -5.10	5.44E-06
LV EF	Measured HDL cholesterol	0.05	-0.25 to 0.35	7.55E-01
LV EF	Genetically-determined HDL cholesterol	0.39	-0.54 to 1.32	4.12E-01
LV mass	Measured HDL cholesterol	2.05	1.35 to 2.74	8.25E-09
LV mass	Genetically-determined HDL cholesterol	-1.97	-4.14 to 0.20	7.48E-02
LV EDV	Measured triglycerides	-5.18	-5.59 to -4.77	1.78E-134
LV EDV	Genetically-determined triglycerides	4.47	2.86 to 6.08	5.61E-08
LV EF	Measured triglycerides	0.23	0.13 to 0.33	5.16E-06
LV EF	Genetically-determined triglycerides	-0.73	-1.12 to -0.34	2.37E-04
LV mass	Measured triglycerides	-0.46	-0.69 to -0.23	7.73E-05
LV mass	Genetically-determined triglycerides	1.79	0.88 to 2.70	1.19E-04

Models are adjusted for age, sex, body surface area and the first 5 genetic principal components. The effect sizes represent the change in LV parameter for every 1 mmol/L increment in lipid concentration.

Supplementary Table 7: One-sample MR results using restricted list of variants in GRS

Lipid parameter	Phenotype	MR effect size	MR 95% CI	MR p value
LDL Cholesterol	LV EDV (ml)	2.12	0.74 to 3.53	0.002
LDL Cholesterol	LV EF (%)	-0.06	-0.39 to 0.26	0.695
LDL Cholesterol	LV mass (g)	1.01	0.24 to 1.78	0.009
Triglycerides	LV EDV (ml)	-0.61	-2.26 to 1.08	0.469
Triglycerides	LV EF (%)	-0.40	-0.8 to 0.001	0.052
Triglycerides	LV mass (g)	1.13	0.21 to 2.08	0.018

One-sample MR data utilising a weighted genetic risk score built using a restricted list of variants following removal of variants which might potentially influence LV remodeling. The total number of included variants is 69, 81 and 50 for LDL, HDL and triglycerides genetic risk scores, respectively. Data is adjusted for age, sex, BSA and the first five principal components and data is presented as change in LV parameter per 39 mg/dL (1 mmol/L) for LDL and HDL cholesterol and 89 mg/dL for triglyceride increase in lifetime lipid parameter exposure.

Supplementary Table 8: Two-sample single instrument and multivariable Mendelian randomization analysis using summary level data

Lipid parameter	Phenotype	Single instrument IVW beta	IVW confidence interval	IVW p-value	Multivariable MR IVW beta	Multivariable MR IVW confidence interval	Multivariable MR IVW p-value
LDL Cholesterol	LV EDV (ml)	1.62	0.32 to 2.91	0.014	1.90	1.13 to 2.67	<0.0001
	LV EF (%)	0.04	-0.17 to 0.25	0.705	0.11	-0.06 to 0.28	0.207
	LV mass (g)	0.66	0.1 to 1.22	0.021	0.55	0.13 to 0.96	0.010
Triglycerides	LV EDV (ml)	-0.43	-1.73 to 0.86	0.512	-1.1	-2.21 to 0.01	0.052
	LV EF (%)	-0.30	-0.66 to 0.06	0.106	-0.23	-0.47 to 0.01	0.060
	LV mass (g)	0.61	0.04 to 1.18	0.036	0.61	0.01 to 1.20	0.047

For two-sample MR the change in LV parameter reflects an increase per 34 mg/dL (0.87 mmol/L) 15 mg/dL (0.38 mmol/L) and 90 mg/dL (1.02 mmol/L) increase in LDL cholesterol, HDL cholesterol and triglycerides, respectively.

Supplementary Table 9: Two-sample MR with MR-Egger, weighted median and weighted mode methods

Lipid parameter	CMR parameter	Egger effect size	Egger confidence interval	Egger p-value	Weighted median effect size	Weighted median confidence interval	Weighted median p-value	Weighted mode effect size	Weighted mode confidence interval	Weighted mode p-value
LDL Cholesterol	LV EDV (ml)	1.90	0.2 to 3.59	0.029	2.12	0.44 to 3.8	0.014	1.93	0.28 to 3.58	0.022
	LV EF (%)	0.12	-0.18 to 0.42	0.422	0.14	-0.19 to 0.48	0.407	0.40	-0.52 to 1.32	0.395
	LV mass (g)	0.32	-0.6 to 1.25	0.497	0.58	-0.27 to 1.43	0.182	0.14	-0.18 to 0.46	0.402
HDL Cholesterol	LV EDV (ml)	1.00	-1.15 to 3.15	0.363	1.26	-0.65 to 3.17	0.195	1.48	-0.38 to 3.34	0.119
	LV EF (%)	0.23	-0.26 to 0.73	0.359	0.26	-0.15 to 0.67	0.209	0.32	-0.12 to 0.76	0.158
	LV mass (g)	0.81	-0.12 to 1.73	0.087	0.36	-0.62 to 1.35	0.472	0.63	-0.39 to 1.65	0.227
Triglycerides	LV EDV (ml)	0.14	-1.82 to 2.1	0.886	-0.96	-3.04 to 1.12	0.365	-0.32	-2.41 to 1.76	0.762
	LV EF (%)	-0.27	-0.86 to 0.33	0.380	0.05	-0.44 to 0.53	0.851	0.11	-1.1 to 1.33	0.858
	LV mass (g)	0.09	-0.74 to 0.93	0.824	0.33	-0.75 to 1.4	0.549	-0.18	-0.67 to 0.32	0.487

For two-sample MR the change in LV parameter reflects an increase per 34 mg/dL (0.87 mmol/L) 15 mg/dL (0.38 mmol/L) and 90 mg/dL (1.02 mmol/L) increase in LDL cholesterol, HDL cholesterol and triglycerides, respectively.

Supplementary Table 10: MR pleiotropy residual sum and outlier (MR-PRESSO) analysis for horizontal pleiotropy

Lipid parameter	Phenotype	Global p-value	Original beta	Original CI	Original p-value	Corrected beta	Corrected CI	Corrected p-value	Distortion p-value
LDL Cholesterol	LV EDV	<0.0001	1.62	0.32 to 2.91	0.014	1.61	0.46 to 2.76	0.007	0.788
	LV EF	0.3824	0.04	-0.17 to 0.25	0.705	No outliers			
	LV mass	0.0314	0.66	0.1 to 1.22	0.021	No outliers			
HDL cholesterol	LV EDV	<0.0001	1.16	-0.07 to 2.39	0.065	0.98	-0.41 to 2.37	0.169	0.38
	LV EF	0.0042	0.18	-0.08 to 0.44	0.184	0.17	-0.11 to 0.44	0.233	0.764
	LV mass	0.0018	0.32	-0.26 to 0.89	0.279	0.32	-0.37 to 1.01	0.37	0.711
Triglycerides	LV EDV	0.0356	-0.43	-1.73 to 0.86	0.512	-0.48	-1.85 to 0.89	0.496	0.39
	LV EF	0.0417	-0.3	-0.66 to 0.06	0.106	No outliers			
	LV mass	0.1318	0.61	0.04 to 1.18	0.036	No outliers			

Supplementary Table 11: MR-Steiger analysis

Exposure	Outcome	SNP r^2 for exposure	SNP r^2 for outcome	Directionality test	MR-Steiger p-value
	LV EDV (ml)	0.0879	0.0106	TRUE	1.30×10^{-138}
LDL Cholesterol	LV EF (%)	0.0879	0.0061	TRUE	7.50×10^{-174}
	LV mass (g)	0.0879	0.0078	TRUE	1.03×10^{-158}
	LV EDV (ml)	0.0570	0.0057	TRUE	3.27×10^{-96}
Triglycerides	LV EF (%)	0.0570	0.0057	TRUE	7.03×10^{-96}
	LV mass (g)	0.0570	0.0053	TRUE	1.48×10^{-99}

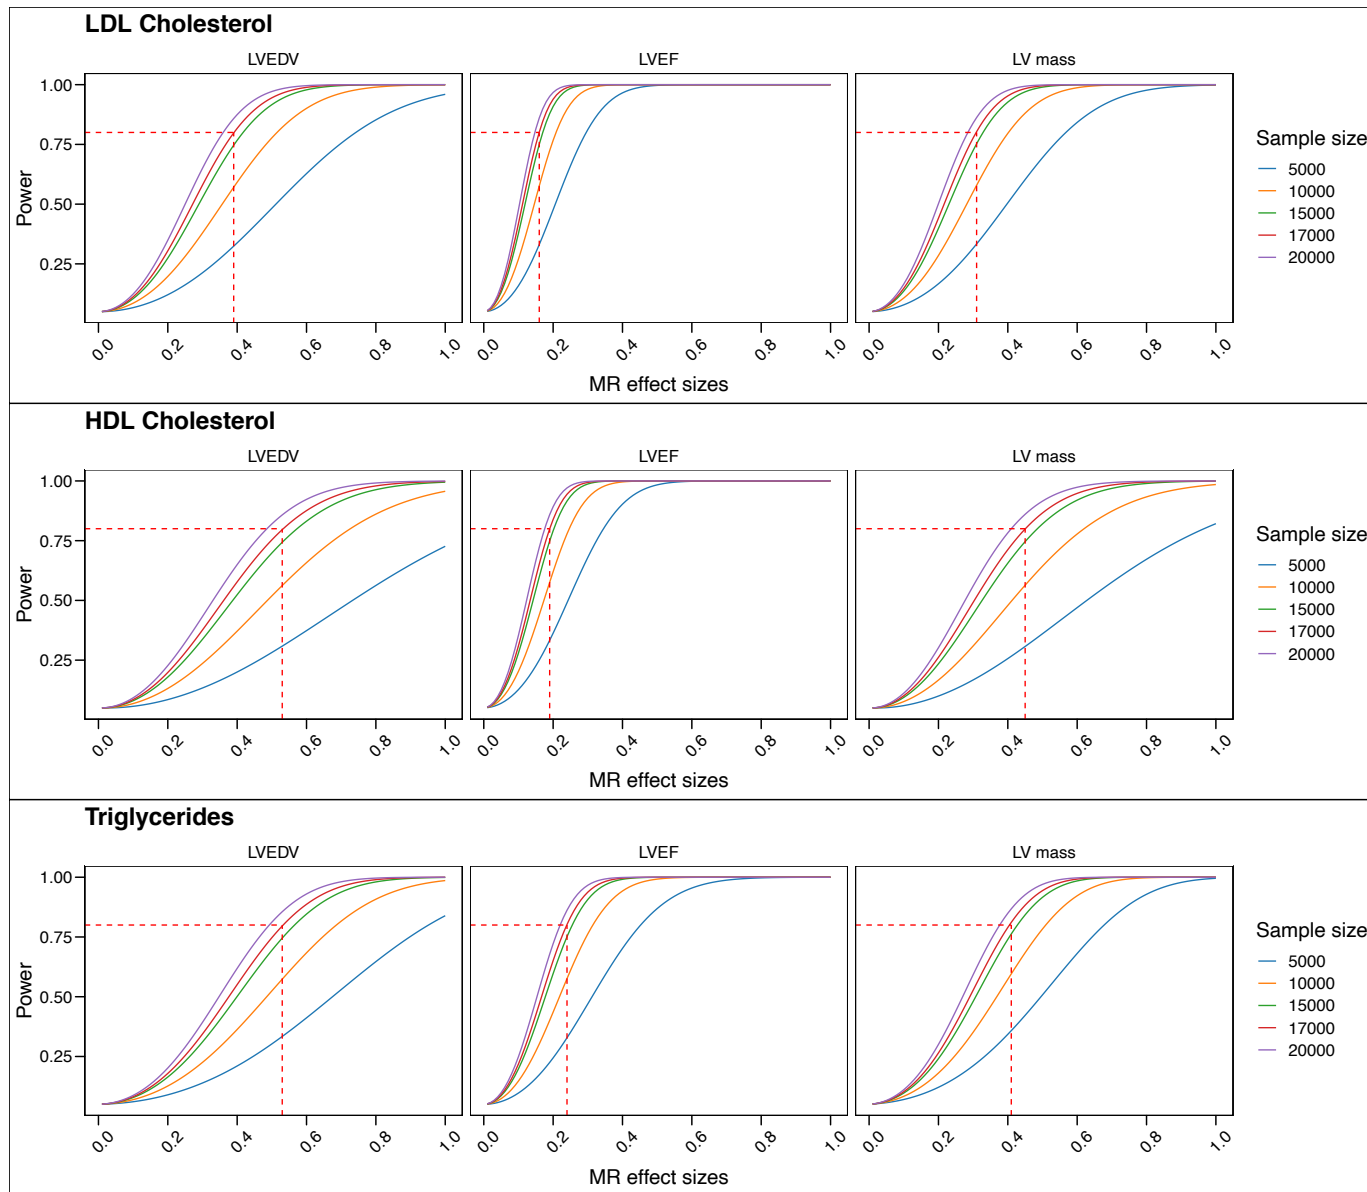

Supplementary Table 12. Interaction analysis of the statin therapy on the relationships between the genetic risk score for LDL cholesterol and LV parameters

Lipid parameter	CMR parameter	Interaction effect size	Interaction standard error	Interaction p-value
	LV EDV (ml)	0.26	0.50	0.610
LDL Cholesterol	LV EF (%)	-0.19	0.12	0.110
	LV mass (g)	-0.07	0.27	0.788

Supplementary Table 13: The variance of phenotypic LV parameters explained by observed lipid measurements and lipid genetic risk scores

Lipid parameter	Phenotype	R ²
Variance of LV phenotypes explained by measured lipids		
LDL Cholesterol	LV EDV	0.35%
	LV EF	0.06%
	LV mass	0.10%
HDL Cholesterol	LV EDV	6.46%
	LV EF	1.68%
	LV mass	14.48%
Triglycerides	LV EDV	0.60%
	LV EF	0.18%
	LV mass	5.42%
Variance of LV phenotypes explained by GRS		
LDL Cholesterol	LV EDV	0.01%
	LV EF	0.00%
	LV mass	0.00%
HDL Cholesterol	LV EDV	0.01%
	LV EF	0.01%
	LV mass	0.00%
Triglycerides	LV EDV	0.00%
	LV EF	0.04%
	LV mass	0.01%
