Return to work after maternity leave: The role of support policies on work attitudes of women in management positions
TITLE

Return to work after maternity leave: The role of support policies on work-family conflict and work attitudes of women in management positions.
RETURN TO WORK AFTER MATERNITY LEAVE

ABSTRACT

Purpose. This study is intended to expand our knowledge on the processes through which work-family policies relate to work-family conflict as well as work-related attitudes among women in management positions returning to work after maternity leave.

Design. Two-hundred and thirty-eight women in management positions who recently have returned to work after maternity leave completed a self-report questionnaire.

Findings. Results show that the availability of policies was either directly or indirectly positively related to work attitudes among female managers. Also, findings show that work-family conflict partially mediates the relationship between the availability of communication and psychological support and flexible time management policies with work engagement, and policy availability moderates the relationship between work-family conflict and work engagement.

Originality/value. Managers have a crucial role in conveying the value of work-family policies and in creating a culture supporting the management of work and family. By investigating the processes underlying the role of work-family policies in influencing work attitudes of women in managerial positions, this study sheds light on how the awareness of the available policies might be an important determinant of work-related well-being and organizational commitment.
RETURN TO WORK AFTER MATERNITY LEAVE

INTRODUCTION

With an increasing number of women in the workforce and the rise of dual-income earners over the last decades (Allen et al., 2014), organizations have started to propose policies aiming to help employees manage work and family more effectively (Clark, Rudolph, Zhdanova, Michel, & Baltes, 2017). Research has provided ample evidence of the role of work-family support policies (WFP) in affecting employees’ work attitudes (Butts, Casper, & Yang, 2013; Kelly et al., 2008). However, the understanding of the mechanisms behind such influence remains elusive and requires more systematic investigations (Rofcanin, Las Heras, & Bakker, 2017; Paustian-Underdahl & Halbesleben, 2014). Studies investigating how WFP are mediated, translated, and enacted in the workplace highlight the key role of managers in shaping the use of existing policies within organizational contexts (ter Hoeven, Miller, Peper, & den Dulk, 2017; Kossek, Lewis, & Hammer, 2010). Yet, research conducted to investigate how supervisors may be involved in WFP mainly focused on their role as models who provide emotional and instrumental support to employees (Hammer, Kossek, Zimmerman, et al., 2007; Hammer, Kossek, Yragui, et al., 2009). While supervisors’ behavior (when perceived as family supportive) reduces work-family conflict, turnover intentions (Kossek, Pichler, Hammer, & Bodner, 2011), and increases job satisfaction and supervisor ratings of employee job performance (Hammer et al., 2009; 2013; Odle-Dusseau et al., 2012), a perspective that focuses on managers’ perceptions of WFP has not received adequate attention in the literature. Hence, little is known about how the availability of WFP influences work attitudes among those in management positions.

The present study aims at increasing this knowledge by investigating the validity of a model linking WFP, work-family conflict, and attitudes among managers who are likely to be highly influential in shaping employees’ interpretation and enactment of WFP, i.e., women in management positions who recently become mothers. Understanding of the role of WFP in
RETURN TO WORK AFTER MATERNITY LEAVE

managing work-family responsibilities and how WFP relate to work outcomes is even more important with regards to managers who are also mothers because they can influence employee awareness of policies and whether using these policies impairs career progress (Butts et al., 2013). Previous research reported that the interference between work and family commitments and responsibilities (i.e., work-family conflict; Frone, 2003) can be related to the slow advancement of women into management positions (Brown, 2010; Schueller-Weidekamm & Kautzky-Willer, 2012). Accordingly, a mother’s organizational re-entry after maternity leave epitomizes a career phase in which the struggle to balance work and family demands can produce psychological distress, increasing work-family conflict and reducing occupational attainment (Jaeckel, Seiger, Orth, & Wiese, 2012). Such a transition in an organizational context represents a critical turning point in many women’s lives (Millward, 2006), which inevitably influences individual and collective opinions in policy and decision-making processes (Schueller-Weidekamm & Kautzky-Willer, 2012).

Understanding the role of WFP during women’s organizational re-entry after maternity leave holds importance, especially within national contexts in which the gender gap in pay and employment rates is far from being narrowed. This is the case in Italy, where the present study was conducted. According to the Global Gender Gap Report 2020 (World Economic Forum, 2019), Italy ranks 76 out of the 153 countries considered worldwide with regards to the gap between men and women across economic participation and opportunity, educational attainment, health and survival, and political empowerment. In Europe, the overall ranking of Italy is higher only compared to Greece, Malta, and Cyprus (World Economic Forum, 2019). Data from 2019 show that, despite a higher percentage of women enrolled in tertiary education compared to men (respectively 71.5% vs. 53%) and an almost equal percentage of literacy rate (99% vs. 99.4%), such educational attainments do not translate to women’s equal participation to the labor force (respectively 55.7% vs. 74.9%), estimated earned income, and involvement.
RETURN TO WORK AFTER MATERNITY LEAVE

in professional roles in terms of senior officials and managers (respectively 27% vs. 73%; World Economic Forum, 2019). Against this background, research on the potential role for WFP in relation to work perceptions after maternity leave and in a sample of female managers holds important implications for policymakers aiming to reduce the gender gap concerning the development of professional trajectories.

This study contributes to advance our understanding of female leaders’ return to work after maternity leave, yielding implications for both theoretical advancement and policy development. First, we shed light on how female managers who are personally involved in balancing work-family issues experience positive outcomes based on the availability of dedicated policies. Furthering knowledge on such aspects is crucial given that leaders facing the challenges of returning to work after motherhood are likely to identify with employees in the same situation (cf. social identity theory, Ashforth & Mael, 1989). In turn, this can lead to the creation of a supportive environment in which managers, identified as group leaders (Chrobot-Mason, Ruderman, Weber, & Ernst, 2009), value employees who are striving for a better equilibrium between work and family life (O’Driscoll et al., 2003; Allen, 2001; Thompson, Beauvais, & Lyness, 1999), eventually resulting in mutually beneficial outcomes for managers and firms alike (Kossek & Friede, 2006). Second, while prior studies have mainly focused on the investigation of the direct relationship between policies and job satisfaction (Greenhaus, Ziegert, & Allen, 2012; Kossek, Pichler, Bodner, & Hammer, 2011), the current study extends this research by proposing and testing a process model that considers both mediation and moderation mechanisms behind the role of the availability of WFP in ultimately influencing work attitudes. Understanding the pattern of relationships linking the availability of WFP to work-family conflict and subsequently to work attitudes (i.e., work engagement and organizational commitment) holds implications for the development of organizational initiatives and intervention strategies based on the factors that drive these outcomes (Shockley...
RETURN TO WORK AFTER MATERNITY LEAVE

& Singla, 2011). Specifically, we argue that WFP represent a job resource likely to influence work attitudes not only through a direct path but also as a buffering factor limiting the negative effects of work-family conflict. Our theoretical model is illustrated in Figure 1.

Third, while previous meta-analyses reported mixed findings regarding the hypothesis that single policies were more strongly related to reduced work-family conflict than multiple ones (Butts et al., 2013), the need for investigating the role of different policy types on work-family conflict still requires empirical investigation (Sutton & Noe, 2005). Moreover, recent research posits that policies differ in the way they convey organizational control, with enabling policies giving employees latitude over when, where and how much they work, and enclosing policies that, on the other side, aim to maximize employees’ availability for work by providing services that remove employees’ need to leave work (Bourdeau, Ollier-Malaterre, & Houlfort, 2019; Friedman, 2001). This study sets out to provide a first empirical investigation of the extent to which different bundles of policies relate to work-family conflict and different work attitudes. In doing so, this research contributes to advance theoretical and practical knowledge on the types of programs to be implemented in order to facilitate return to work after maternity leave.

THEORETICAL BACKGROUND

The relationship between work-family policies and work attitudes

Reflecting the changing workforce demographics, organizations have recently become more responsive to work-family issues, offering a more extensive array of formal WFP (Clark, Rudolph, Zhdanova, Michel, & Baltes, 2017). Work-family support policies represent one of the means through which organizations may respond to employee family needs (Swody &
RETURN TO WORK AFTER MATERNITY LEAVE

Powell, 2007), providing support to reduce conflicts and stress related to employees fulfilling multiple roles in life (Kossek, 2005). When role demands from one domain are incompatible with role demands in the other domain, this may result in adverse interactions between work and family (Greenhaus & Beutell, 1985).

Work-family conflict is highly probable to occur among employed parents who represent a group of people likely to feel the burden of multiple demands from work and non-work domains (Brough, O’Driscoll, & Biggs, 2009). Previous findings report that mothers are more vulnerable to role conflicts (Brough & O’Driscoll 2005; Brown, 2010; Freudenburg & Davidson, 2007; Losoncz & Bortolotto, 2009; Somech & Drach-Zahavy, 2007), which can be explained according to resource-drain theory postulating that personal resources are finite, and resources expended in one domain are not available in another (Edwards & Rothbard, 2000). That is, resource drain is likely to impact working mothers in the face of competing multiple-role demands, resulting in stress-related outcomes such as work-family conflict (Michel, Kotrba, Mitchelson, Clark, & Baltes, 2011). Women in leadership positions are likely hit especially hard by work-family conflict as these positions entail a significant amount of responsibility to the company’s financial performance, and female managers are more highly scrutinized than their male counterparts (Hoobler, Masterson, & Nkomo, 2018).

Building on the job demands-resources theory (JD-R; Bakker & Demerouti, 2007), we conceptualize WFP as a job resource. The JD-R assumes that all job characteristics within the work environment can be classified into job demands and job resources. Job demands are defined as “those physical, social, or organizational aspects of the job that require sustained physical or mental effort and are therefore associated with certain physiological and psychological costs” (Demerouti et al., p. 501). On the other side, job resources are conceptualized as “those physical, social, or organizational aspects of the job that either are functional in achieving work goals; reduce job demands and the associated physiological and
RETURN TO WORK AFTER MATERNITY LEAVE

psychological costs; or stimulate personal growth and development” (Demerouti et al., 2001, p.501). Whereas job demands are generally the most important predictors of negative work-related outcomes such as exhaustion (Bakker, Demerouti, & Schaufeli, 2003), job resources are generally the most important predictors of work motivation and engagement (Bakker et al., 2007).

Scholars argue that job resources are instrumental in achieving work goals and that they play an intrinsic motivational role because they satisfy the basic human need for either autonomy, relatedness, or competence (Schaufeli & Taris, 2014; Deci & Ryan, 2000). In this study, we argue that WFP can represent a means to achieve work goals, for example, when they are perceived as allowing better time-management or a means through which satisfying one’s basic need, e.g., the one for autonomy when they refer to flexible work arrangements. Accordingly, we place WFP as a specific job resource that, if coupled with others such as social support, development opportunities, and performance feedback, can serve to stimulate positive work attitudes and reduce the negative impact of work-family conflict (Mauno, Kinnunen, & Ruokolainen, 2006). Research suggests that adopting the JD-R to the study of organizational policies can provide important insights to the design, implementation, and monitoring of such policies because it sheds light on the psychological processes underlying the development of work and organization outcomes associated with perceived resources and demands (Costantini, Sartori, & Ceschi, 2017). That is, in the context of this study, such a framework allows understanding whether and how specific WFP facilitate female managers’ coping with the job demands associated with motherhood, and if the availability of WFP can be particularly helpful at different levels of such perceived demands, eventually serving to support (or not) higher work-related well-being (Bakker et al., 2003).

In line with such a conceptualization, previous findings showed that the availability of WFP exhibits small but favorable relationships with positive work attitudes (Butts et al., 2013),
RETURN TO WORK AFTER MATERNITY LEAVE

intentions to stay in the job (Thompson & Prottas, 2006), and a negative relationship with work-family conflict (Thompson et al., 1999). Accordingly, we propose the following:

Hypothesis 1: Policy availability negatively relates to work-family conflict.

Drawing on signaling theory (Spence, 1973), the availability of WFP may be interpreted as a symbol of corporate concern to employees’ family needs, likely to prompt positive work attitudes (Butts et al., 2013). That is, employees may interpret WFP as signals of corporate concern for their employees’ well-being, thereby forming impressions about a company’s motives (Goldberg & Allen, 2008). In turn, employees who feel supported by their organizations may feel obliged to reciprocate, which would translate into positive work and organization outcomes (Blau, 1964; Kossek & Thompson, 2016). Past findings support this argumentation, particularly with regards to the relationship between the availability of work-life benefits and increased organizational commitment (Allen, 2001; Behson, 2005; Casper & Harris, 2008; Grover & Crooker, 1995). Similarly, work engagement, which is substantially influenced by job resources (Schaufeli & Bakker, 2004), i.e., WFP, will be positively related to policy availability. Based on this, we propose the following:

Hypothesis 2: Policy availability positively relates to (a) affective commitment, (b) work engagement, (c) continuance commitment.

Work-family conflict and its relationship with work attitudes

Work-family conflict represents the most commonly studied experience at the work-family interface. Even if it has been defined as inherently non-directional (Greenhaus & Beutell, 1985), once a decision is made for resolving the conflict, it usually results in work-to-family interference (WFI) or family-to-work interference (Grzywacz & Smith, 2016). Several studies investigated how these different forms of conflict relate to organizational outcomes. Findings reported that WFI is positively related to continuance commitment (Casper et al., 2002; Lyness & Thompson, 1997) and that it predicts job dissatisfaction. Such a relationship has been argued
RETURN TO WORK AFTER MATERNITY LEAVE

to reflect the fact that employees who experience WFI, yet remain employed with their organizations, may attribute their commitment to aspects of “need” (i.e., they feel that they need to continue working in that environment; continuance commitment), as opposed to aspects related to “want” (i.e., the feeling of wanting to work in that environment). This may also suggest that mothers who experience WFI remain with their organizations out of necessity rather than choice (Casper et al., 2002). Research also reported evidence of a negative relationship between WFI and affective commitment, as well as with work engagement (Good, Sisler, & Gentry, 1988; Lyness & Thompson, 1997; Opie & Henn, 2013; Thompson et al., 1999).

Literature defines affective commitment as denoting an emotional attachment to the organization and continuance commitment as denoting the perceived costs associated with leaving it. Since WFI represents the type of conflict originating in the work domain, it may be associated with lower emotional attachment (i.e., affective commitment) to the organization (Casper et al., 2002). Moreover, drawing on findings supporting a source attribution perspective in linking WFI and attitudes (Shockley & Singla, 2011), it is likely that people would blame the organization for work interfering with family, eventually reporting lower intention to continue, i.e., lower continuance commitment.

Hypothesis 3: WFI negatively relates to (a) affective, and (b) continuance commitment.

Although an extensive body of literature investigated the relationship between WFI and several work outcomes, less attention has been paid to the study of the link between WFI and work engagement. Studies investigating the role of work engagement inside organizations showed its relevance for employees’ well-being and work behavior (Sonnenstag, 2003) and that engaged employees transfer their engagement to others in their immediate environment (Bakker & Xanthopoulou, 2009). Even though work engagement does not represent a recurrent outcome associated with WFI, one notable exception is the study conducted by Opie and Henn (2013),
who reported that WFI negatively predicts work engagement among mothers. Considering these findings, we propose that:

_Hypothesis 3c:_ WFI negatively relates to work engagement.

**A model of the psychological mechanisms between work-family policies, work-family conflict, and work attitudes**

Building on the relationships described in the previous hypotheses, work-family conflict represents a mediator of the relationship between WFP and work attitudes. Accordingly:

_Hypothesis 4:_ Work-family conflict mediates the relationship between the availability of WFP and work attitudes, i.e., organizational commitment and work engagement.

Moreover, drawing on the JD-R framework, we expect that the availability of different bundles of WFP will buffer the negative effects of WFI on affective commitment and work engagement. Indeed, previous findings reported that WFP relate to employee outcomes through lower work-life conflict (Beauregard & Henry, 2009). Along with previous hypotheses, this argument involves a moderated mediation process (MacKinnon, 2008; MacKinnon & Fairchild, 2009; Muller, Judd, & Yzerbyt, 2005) where:

_Hypothesis 5:_ The availability of work-family policies buffers the negative relationship between WFI and work attitudes, such that the proposed mediation through work-family conflict is stronger when work-family policies are not available (Figure 1).

**MATERIALS AND METHOD**

**Participants and procedure**

Participation in the study was accomplished via a web-based survey mailed to 345 female managers from different companies operating throughout Italy in a variety of different segments. On average, it took 20 minutes to complete the questionnaire. Table 1 sums up the characteristics of the participants. Potential participants were recruited from a national web-community of female managers, from which we identified those stating in their profile of
RETURN TO WORK AFTER MATERNITY LEAVE

having at least one child under three years old. Of the total number of surveys mailed, 238 questionnaires were considered valid and usable for the study for a response rate of 69%. All participants worked in a managerial position, were mothers, and reported a mode of 1 child. Thirty-seven percent of the participants stated they returned to work within the first six months from delivery, 47.6% within the first year, 10.6% within 18 months from delivery, and 4.2% within 24 months from delivery. The mean age of respondents was 34 years, ranging from 29 to 52.

Each participant was asked to complete questions on demographic and role-related variables (i.e., age, education, company’s sector), and a questionnaire measuring WFI, work-family enrichment, work engagement, and organizational commitment. All participants were given a notice containing a brief explanation of the purpose of the study and a statement ensuring the confidentiality of their results. Items were focused on the moment of organizational re-entry after childbirth by adding the following instruction before each scale: “Please note: These questions are about your overall situation since your return to work after maternity leave. Fill in the statements thinking about how you felt since you came back to work after your youngest child was born.” Question order was counterbalanced to avoid common method bias (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003).

Measures

WFI. Work interfering with family was assessed with six items of the short version of the work-family balance scale (Zhang et al., 2012). This scale has been developed based on the shortened version (13 items; Wooden, 2003) of Mashall and Barnett’s (1993) 26-item work-family strains and gains scale, which conceptualizes work-family balance as including work-family enrichment and work-family conflict (Grzywacz & Carlson, 2007). As for work-family
RETURN TO WORK AFTER MATERNITY LEAVE

cost, the items capture aspects referring to work-family and work-parenting strains, i.e.,
multiple overloads and multiple-role conflict (Marshall & Barnett, 1993). A sample item is
“Because of work, I often fail to take part in family activities”. Response options were on a 7-
point rating scale from strongly disagree (1) to strongly agree (7). We also administered the six
items measuring work-family enrichment (WFE) from the same scale. A sample item is “Work
and family together enrich my life.” Results from a Pearson’s correlation indicated that the two
scales were significantly and negatively correlated, $r = -.28; p < .01$, indicating that, in our
sample, those experiencing high WFI also reported low enrichment.

**Work engagement.** Work engagement was assessed with 17-items from the Italian
version of the Utrecht Work Engagement Scale (Pisanti, Paplomatas, & Bertini, 2008). This
version includes six items for the vigor (e.g., “*At my work, I feel bursting with energy*”) and
absorption (e.g., “*I am immersed in my work*”) dimensions, and five items for the dedication
dimension (e.g., “*I am enthusiastic about my job*”). Items were scored on a 7-point rating scale
ranging from 0 (never) to 6 (always). Based on results from Schaufeli, Bakker, and Salanova
(2006), showing that the three dimensions are closely related, we used one overall index for
work engagement (Cronbach’s $\alpha = .96$).

**Organizational commitment.** Seven items developed by Allen & Meyer (1991)
assessed affective and continuance commitment. Three items measured the former (e.g., “*This
organization has a great deal of personal meaning for me*”) and four the latter (e.g., “*I feel that
I have too few options to consider leaving this organization*”). Responses were made on a 7-
point rating scale from strongly disagree (1) to strongly agree (7). Cronbach’s $\alpha$ for the
affective commitment scale was .77, and .79 for the continuance commitment scale.

**Availability of work-family support policies.** We examined multiple policies that
referred to different bundles, e.g., flexible time management, training projects on maternity
leave and organizational re-entry, parenting and pregnancy policies, and organizational
facilities. Participants were asked to indicate whether or not each policy was available in their organizations. Table 2 reports the items used to measure policy availability and the results of an exploratory factor analysis conducted to examine what policies were perceived as referring to the same bundle in participants’ perceptions. After that, policy availability was treated as a count variable, summing the policies available for each bundle extracted from the EFA. In particular, from the results of the EFA we extracted six factors (bundles) and summed the policies referred to each of such bundles: (a) Organizational facilities, which refer to policies aiming at providing employees services and spaces to help manage work and family; (b) Smart working, referring to policies aiming at allowing customization of the way in which working time/space is managed; (c) Parenting and pregnancy policies, which refer to the management of the maternity leave period; (d) Communication and psychological support, referring to the ways in which organizations provide specific measures to support information exchange and psychological support during pregnancy and/or maternity; (e) Flexible time management, referring to part-time arrangements and the management of lunch breaks; (f) Return to work management, which refers to measures allowing a mutual agreement of the return to work phase after maternity leave. Drawing on the assumption that policy availability must be observed by employees to be used (Thompson et al., 2004), policy availability was assessed as an individual-level measure of perceived availability rather than actual availability at the organizational level.

---------------------------

Controls. We controlled for a number of demographic variables, including age, marital status, partner, and number of children. Our results did not change when including these, hence they were excluded from further analyses.

RESULTS
RETURN TO WORK AFTER MATERNITY LEAVE

Table 3 shows the means, standard deviations, internal reliability values, and correlations among the variables of interest.

-----------------------------
INSET TABLE 3 ABOUT HERE
-----------------------------

Before testing our hypotheses, we ran confirmatory factor analyses (CFAs) to explore the factorial structures of our measures using AMOS 21.0 with maximum likelihood estimation (Byrne, 2001). Since our policy measures are here conceptualized as formative constructs, i.e., explanatory combinations of indicators (Bollen & Bauldry, 2011; Fornell & Bookstein, 1982), we did not include them in the CFA. Accordingly, in order to check whether our policy measures were distinct from the other constructs, we checked the correlation matrix. Results (see Table 3) showed that the policy measures are correlated relatively low with the other constructs, indicating that they do not substantially overlap.

As for the CFA, we followed established recommendations to report our findings (Hu & Bentler, 1999; Schumacker & Lomax, 2004; Klein, Tosi, & Cannella, 1999). A model including the five study variables (WFI, WFE, affective commitment, continuance commitment, and work engagement) supported the discriminant validity of our measures: \( \chi^2 (536 \text{ df}) = 831.70, p < 0.001; \) CFI = .93; TLI = .92, RMSEA = .06, SRMR = .08.

-----------------------------
INSET TABLE 4 ABOUT HERE
-----------------------------

Hypotheses 1 stated that policy availability should be negatively related to WFI. Results from regression analyses (see Table 5) revealed a significant negative beta coefficient for communication and psychological support (\( \beta = -.26, p < .01 \)) and flexible time management (\( \beta = -.31, p < .01 \)), providing partial support for Hypotheses 1. Hypotheses 2 predicted that the availability of WFP is positively related to affective and continuance commitment, as well as
RETURN TO WORK AFTER MATERNITY LEAVE

work engagement. Results from regression analyses revealed that the availability of organizational facilities ($\beta = .24, p < .01$), communication and psychological support ($\beta = .30, p < .01$), and flexible time management ($\beta = .33, p < .001$) positively predicted affective commitment, partially supporting Hypothesis 2a. The availability of organizational facilities ($\beta = .32, p < .001$), communication and psychological support ($\beta = .26, p < .01$), and flexible time management ($\beta = .32, p < .05$) was also found to be positively related to work engagement, partially confirming Hypothesis 2b. As for Hypothesis 2c, results showed that the availability of communication and psychological support ($\beta = -.29, p < .01$) and flexible time management ($\beta = -.27, p < .01$) negatively predicted continuance commitment. Hypotheses 3 stated that WFI is negatively related to organizational commitment and work engagement. Results from the regression analyses showed that continuance commitment was positively related to WFI ($\beta = .35, p < .001$), while work engagement and affective commitment were negatively related to WFI (respectively: $\beta = -.32, p < .001$; $\beta = -.30, p < .001$).

---------------------------
INSERT TABLE 5 ABOUT HERE
---------------------------

Hypothesis 4 investigated the mediating role of WFI in the relationship between the availability of WFP and work attitudes. In order to test such a Hypothesis, we used a bootstrap estimation approach with 5000 samples (Preacher & Hayes, 2008). Results are reported in Table 6 and show that, depending on the policy considered, WFI acts as a full mediator between policy availability and work attitudes. Findings showed that the availability of organizational facilities was no longer a significant predictor of affective commitment after controlling for WFI, $B = .57, SE = .26, ns$, consistent with a full mediation. Likely, after controlling for WFI, flexible time management policies were no longer significantly associated with continuance commitment, $B = -.33, SE = .18, ns$. The availability of parenting and pregnancy policies
RETURN TO WORK AFTER MATERNITY LEAVE

showed to be positively related to work engagement only when controlling for WFI, $B = .66$, $SE = .28$, 95% CI = .09, 1.22, consistent with a partial mediation.

Finally, Hypothesis 5 stated that the availability of WFP moderates the mediation through WFI. To test this Hypothesis, we utilized bootstrapping (Shrout & Bolger, 2002), as suggested by MacKinnon, Fairchild, and Fritz (2007). Results are reported in Table 6.

-----------------------------
INSERT TABLE 6 ABOUT HERE
-----------------------------

Results (see Table 7) revealed that among all the different policies considered, the availability of communication and psychological support policies and of flexible time management acted as variables influencing WFI and moderating the effects of conflict on work engagement. That is, the availability of communication and psychological support at the organization was significantly related to WFI ($B = -.48$, $p < .001$), which in turn was significantly related to work engagement ($B = -.32$, $p < .001$). Additionally, flexible time management was significantly related to WFI ($B = -.57$, $p = .001$), which in turn was significantly related to work engagement ($B = -.35$, $p < .001$). As expected, there was a significant indirect effect of both communication and psychological support and flexible time management on work engagement through WFI (respectively: $B = .42$, $p < .05$; 95%CI [.08, .75]; $B = .50$, $p < .01$; 95%CI [.16, .84]), as well as a moderation effect of policy availability on the influence of WFI on work engagement (respectively, for communication and psychological support $B = .35$, $p < .01$; 95%CI [.08, .62], for flexible time management $B = .51$, $p = .001$; 95%CI [.22, .79]). In both cases, the conditional indirect effect was significant for those reporting medium and low levels of WFP. The index of moderated mediation (Hayes, 2015) corresponded to -.17, 95%CI, [-.37, -.04] for communication and psychological support, and -.29, 95%CI, [-.58, -.09] for flexible time management.
DISCUSSION

This study focused on the psychological mechanisms through which the availability of WFP yields beneficial consequences for women in management positions who return to work after maternity leave. Following the basic premises of the JD-R theory (Bakker & Demerouti, 2014), in our study, we considered WFP as a job resource. Moreover, according to the buffering effect postulated in the JD-R theory, we expected WFP to moderate the negative effects of WFI on positive work attitudes, i.e., work engagement and organizational commitment. Our results contribute to the knowledge on how the availability of different bundles of WFP relates to managers’ work attitudes after they return to work following maternity leave, holding importance for both research and practice.

First, by adopting the JD-R theory to the study of boundary management (i.e., the ways in which individuals maintain, negotiate, and transition across work and family roles) from an organizational perspective (Allen, Cho, & Meier, 2014), our study contributes to the field of work-family boundary dynamics by answering the call to increase our understanding of the results and processes underlying the effectiveness of WFP. Moreover, by considering several types of policies, we were able to investigate how they differ in influencing WFI and work attitudes. Recent research suggests that, while WFP are often treated as if they were all created equal, they differ in the way organizational control is conveyed (Bourdeau et al., 2019). Accordingly, scholars argue that de-bundling policies permits to differentiate between enabling and enclosing mechanisms of control and to identify their effects on work attitudes. In our study, we show that different enclosing policies are linked to work attitudes while enabling ones are not. Consistently, our findings show that communication and psychological support, and flexible time management were either directly or indirectly related to work attitudes. Such policies represent enclosing ones, in that they encourage the management of maternity leave.
RETURN TO WORK AFTER MATERNITY LEAVE

within rather than outside the organization. Indeed, even though flexible time management may suggest a more enabling mechanism of control, it refers to variations of the time around core business hours when employees must be at work, which is different from smart working policies that, on the contrary, refer to the ability to choose the work time of start/end, and/or the location from which to work (Bourdeau et al., 2019). Such findings may be explained based on the view that the status of motherhood may undermine the credibility of employees’ commitment (Correll, Benard, & Paik, 2007), with women in management positions who return to work valuing organizational support in the form of policies permitting to signal greater work devotion.

In the current study, the availability of communication and psychological support, as well as flexible time management, are both positively related to affective commitment and work engagement, and negatively related to continuance commitment. This may suggest that the availability of such policies is likely to sustain positive affective attitudes referred to the organization, which may counterbalance feelings of instrumental considerations related to continuance commitment. Our study also confirms that WFI is a negative predictor of work engagement. This is consistent with existing literature on the relationship between WFI and burnout (Ahmad, 2010) and WFI and work engagement (Opie & Henn, 2013). Moreover, partially in line with previous research, the current study provides evidence that WFI negatively influences affective commitment (Lyness & Thompson, 1997; Thompson et al., 1999), and positively influences continuance commitment (Casper et al., 2002). While experiencing WFI originating in the work domain is likely to affect emotional attachment to the organization negatively, it is also presumable that mothers who experience such negative situations, yet continue to work with their organization, may attribute such feelings to necessity, rather than choice, eventually reporting higher levels of continuance commitment.
RETURN TO WORK AFTER MATERNITY LEAVE

When considering WFI as a mediator of the relationship between policy availability and work attitudes, organizational facilities show to be no longer significant positive predictors of affective commitment, while flexible time management policies were no longer negatively linked to continuance commitment. That is, WFI undermines the importance of organizational facilities to feel emotionally attached to the organization while also sustaining perceptions referred to the need for staying in an organization because of the perceived costs associated with leaving it. When considering WFI as a mediator between parenting and pregnancy policies and work engagement, the availability of such policies become a significant predictor of higher work engagement, suggesting that such policies are perceived as important when perceptions of WFI are involved.

The current study also provides evidence of a mediated moderation in which WFI partially mediates the relationship between the availability of communication and psychological support and flexible time management policies with work engagement, and policy availability moderates the relationship between WFI and work engagement. That is, for female managers working in organizations where such policies are available, the effects of WFI on work engagement are lowered. This may suggest that working mothers who experience WFI in organizations where these policies are available are more likely to experience a positive, fulfilling, work-related state of mind, which allows them to be absorbed into their work and focused less on the negative impact of the competing role demands between work and family domains. Flexible time management and communication and psychological support are useful not only to reduce conflict, either symbolically or actually (Kossek & Ozeki, 1998), but also to buffer the negative effects of conflict on work engagement. These findings support the assumptions of the JD-R theory, which hold that job resources are useful to attain work goals and to buffer the negative effects of perceived demands (i.e., WFI) on motivational states (Bakker & Demerouti, 2017). Moreover, results suggest possible avenues for enhancing the use
RETURN TO WORK AFTER MATERNITY LEAVE

of JD-R theory as a model to improve work-life initiatives by detailing the psychological mechanisms through which these might be effective in sustaining work-related well-being. Our findings show that female managers’ positive work perceptions after motherhood can be sustained via the provision of WFP because these can lower perceptions of work-family conflict and its effect on motivational states. This suggests that such policies may be perceived as particularly powerful symbols among our participants because they provide organizational mechanisms to manage the boundaries of the work-family interface. In turn, this is likely to lower perceptions of WFI, because the awareness that the organization provides chances to manage the increased responsibilities and maintain a good work reputation is likely to alleviate the pressure from the participation in multiple roles.

Finally, our study provides valuable insights about which policies can stimulate positive work attitudes that are likely to be transferred to others in the immediate environment, i.e., work engagement (Bakker & Xanthopoulou, 2009). Accordingly, offering policies that increase work engagement among managers may yield multiplicative benefits, which may spread to the entire organization. Previous evidence showed that when managers were viewed as being understanding and supportive of employees’ needs, individuals experienced not only less conflict between their work and family life but also greater commitment to their organization and higher levels of job satisfaction (O’Driscoll et al., 2003).

Overall, findings suggest that the JD-R approach can be used to advance the literature on work-life balance by shedding light on the indirect and interactive effects of certain WFP on different positive and negative outcomes. This is particularly relevant given that, to date, the majority of studies on work interfering with family have focused only on direct relationships between work-family conflict and its outcomes (Rofcanin et al., 2017; Mauno et al., 2006). On the other side, such an approach also contributes to advance the JD-R theory by showing that “hybrid” crossover factors spanning different life domains. That is, policies and initiatives
RETURN TO WORK AFTER MATERNITY LEAVE

designed to support the daily management of responsibilities from spheres that are not limited to the work environment can have a significant role in sustaining motivational processes in the workplace.

Limitations and future research

Given the nature of the study, several limitations need to be considered when evaluating the results. First, the conclusions we draw from the present research are based on a relatively homogenous sample of Italian managers, which might affect the transcultural validity of our results. Also, even though our study offers some initial insights to understand the role of different enclosing and enabling policies on the development of work and organization outcomes, more research is needed to test whether the results would differ among other populations and controlling for policy use. Given that we collected measures on policy availability rather than use, our study suggests that employees’ awareness and interpretation of the signals sent through the availability of WFP can have an effect on both work engagement and commitment. Accordingly, organizations’ intentions to be supportive could also be signaled through different means that leverage, for example, on interpersonal communication and everyday acts (Grandey, Cordeiro, & Michael, 2007), which could be investigated in future studies.

Moreover, even though our results provide valuable insights into the role of WFP in fostering work engagement and affective commitment while lowering WFI among female managers with children, future research should try to replicate our study on participants including also males and participants without children, in order to compare results from different groups (e.g. single female managers without children or those who have taken maternity leave some time ago). Also, while our participants were all mothers, we were not able to control for the effects of domestic and child-care help of participants’ role as primary caregivers. Research in this area may provide further insights to develop programs and policies...
RETURN TO WORK AFTER MATERNITY LEAVE

targeted at the specific needs of organization members and accounting for their responsibilities
in different life domains.

Although the cross-sectional data from our field study does not allow to draw definite
causal conclusions (Butts et al., 2013) and reverse causality is possible (e.g., WFI influences
the perception of WFP), our study was conceptualized under the premise that it is easier for
companies to manipulate the presence of WFP and investigate the effects it has on WFI. Future
studies should manipulate the presence of WFP experimentally to examine the causal direction
in more detail. Moreover, future research could consider collecting data from both managers
and employees in order to understand how managers’ experiences with WFP impact on their
perceptions of employees using leave.

Finally, our study does not allow to draw conclusions about the extent to which our
participants’ responses reflect the genuine choices of women in managerial roles returning to
work after maternity leave rather than adherence to established norms regarding appropriate
managerial roles. In this vein, it could be argued that WFP might indirectly serve to perpetuate
stereotypical working patterns rather than to decrease women’s work-family conflict. Research
in this area is needed to shed light on how WFP actually help in reducing work-family conflict,
also depending on how WFP are experienced, interpreted, and used in possibly different ways.
Along this line, future studies could also consider investigating whether the experienced quality
of the provided policy has a role over work-related attitudes and work-family conflict.

CONCLUSIONS AND PRACTICAL IMPLICATIONS

The availability of communication and psychological support, as well as flexible time
management, may result in higher affective commitment and work engagement for women in
management positions who return to work after maternity leave. Moreover, this study shows
that the availability of flexible time management and communication and psychological support
lowers WFI and buffers its negative effect on work engagement.
RETURN TO WORK AFTER MATERNITY LEAVE

These findings yield practical implications for developing HR policies aiming at supporting the return to work after maternity leave. Although appointing women to leadership roles within organizations can symbolize a modern approach to management (Eagly & Carli, 2003), we argue that organizational structures need to be in place in order to accommodate a healthy work-life balance. Specifically, results indicate that organizations may support work-related psychological well-being of women in management positions who recently become mothers by (a) offering services and spaces to facilitate the efficient management of work and family, (b) providing measures to support information exchange and psychological support during pregnancy and maternity, and (c) offering part-time arrangements and flexible management of breaks. Within current organizations, managers’ commitment to their occupation leads to the proper delivery and implementation of organization practices and, therefore, is deemed as a critical factor for the success of such practices (Oh, Blau, Han, & Kim, 2017). This may be especially interesting for countries with meager fertility rates and available support such as Italy, where women who experienced maternity and hold high responsibilities at work can contribute to reshaping discussions of women at work.

TITLE

Return to work after maternity leave: The role of support policies on work-family conflict and work attitudes of women in management positions.
RETURN TO WORK AFTER MATERNITY LEAVE

ABSTRACT

Purpose. This study is intended to expand our knowledge on the processes through which work-family policies relate to work-family conflict as well as work-related attitudes among women in management positions returning to work after maternity leave.

Design. Two-hundred and thirty-eight women in management positions who recently have returned to work after maternity leave completed a self-report questionnaire.

Findings. Results show that the availability of policies was either directly or indirectly positively related to work attitudes among female managers. Also, findings show that work-family conflict partially mediates the relationship between the availability of communication and psychological support and flexible time management policies with work engagement, and policy availability moderates the relationship between work-family conflict and work engagement.

Originality/value. Managers have a crucial role in conveying the value of work-family policies and in creating a culture supporting the management of work and family. By investigating the processes underlying the role of work-family policies in influencing work attitudes of women in managerial positions, this study sheds light on how the awareness of the available policies might be an important determinant of work-related well-being and organizational commitment.
RETURN TO WORK AFTER MATERNITY LEAVE

INTRODUCTION

With an increasing number of women in the workforce and the rise of dual-income earners over the last decades (Allen et al., 2014), organizations have started to propose policies aiming to help employees manage work and family more effectively (Clark, Rudolph, Zhdanova, Michel, & Baltes, 2017). Research has provided ample evidence of the role of work-family support policies (WFP) in affecting employees’ work attitudes (Butts, Casper, & Yang, 2013; Kelly et al., 2008). However, the understanding of the mechanisms behind such influence remains elusive and requires more systematic investigations (Rofcanin, Las Heras, & Bakker, 2017; Paustian-Underdahl & Halbesleben, 2014). Studies investigating how WFP are mediated, translated, and enacted in the workplace highlight the key role of managers in shaping the use of existing policies within organizational contexts (ter Hoeven, Miller, Peper, & den Dulk, 2017; Kossek, Lewis, & Hammer, 2010). Yet, research conducted to investigate how supervisors may be involved in WFP mainly focused on their role as models who provide emotional and instrumental support to employees (Hammer, Kossek, Zimmerman, et al., 2007; Hammer, Kossek, Yragui, et al., 2009). While supervisors’ behavior (when perceived as family supportive) reduces work-family conflict, turnover intentions (Kossek, Pichler, Hammer, & Bodner, 2011), and increases job satisfaction and supervisor ratings of employee job performance (Hammer et al., 2009; 2013; Odle-Dusseau et al., 2012), a perspective that focuses on managers’ perceptions of WFP has not received adequate attention in the literature. Hence, little is known about how the availability of WFP influences work attitudes among those in management positions.

The present study aims at increasing this knowledge by investigating the validity of a model linking WFP, work-family conflict, and attitudes among managers who are likely to be highly influential in shaping employees’ interpretation and enactment of WFP, i.e., women in management positions who recently become mothers. Understanding of the role of WFP in
RETURN TO WORK AFTER MATERNITY LEAVE

managing work-family responsibilities and how WFP relate to work outcomes is even more important with regards to managers who are also mothers because they can influence employee awareness of policies and whether using these policies impairs career progress (Butts et al., 2013). Previous research reported that the interference between work and family commitments and responsibilities (i.e., work-family conflict; Frone, 2003) can be related to the slow advancement of women into management positions (Brown, 2010; Schueller-Weidekamm & Kautzky-Willer, 2012). Accordingly, a mother’s organizational re-entry after maternity leave epitomizes a career phase in which the struggle to balance work and family demands can produce psychological distress, increasing work-family conflict and reducing occupational attainment (Jaeckel, Seiger, Orth, & Wiese, 2012). Such a transition in an organizational context represents a critical turning point in many women’s lives (Millward, 2006), which inevitably influences individual and collective opinions in policy and decision-making processes (Schueller-Weidekamm & Kautzky-Willer, 2012).

Understanding the role of WFP during women’s organizational re-entry after maternity leave holds importance, especially within national contexts in which the gender gap in pay and employment rates is far from being narrowed. This is the case in Italy, where the present study was conducted. According to the Global Gender Gap Report 2020 (World Economic Forum, 2019), Italy ranks 76 out of the 153 countries considered worldwide with regards to the gap between men and women across economic participation and opportunity, educational attainment, health and survival, and political empowerment. In Europe, the overall ranking of Italy is higher only compared to Greece, Malta, and Cyprus (World Economic Forum, 2019). Data from 2019 show that, despite a higher percentage of women enrolled in tertiary education compared to men (respectively 71.5% vs. 53%) and an almost equal percentage of literacy rate (99% vs. 99.4%), such educational attainments do not translate to women’s equal participation to the labor force (respectively 55.7% vs. 74.9%), estimated earned income, and involvement
RETURN TO WORK AFTER MATERNITY LEAVE

in professional roles in terms of senior officials and managers (respectively 27% vs. 73%; World Economic Forum, 2019). Against this background, research on the potential role for WFP in relation to work perceptions after maternity leave and in a sample of female managers holds important implications for policymakers aiming to reduce the gender gap concerning the development of professional trajectories.

This study contributes to advance our understanding of female leaders’ return to work after maternity leave, yielding implications for both theoretical advancement and policy development. First, we shed light on how female managers who are personally involved in balancing work-family issues experience positive outcomes based on the availability of dedicated policies. Furthering knowledge on such aspects is crucial given that leaders facing the challenges of returning to work after motherhood are likely to identify with employees in the same situation (cf. social identity theory, Ashforth & Mael, 1989). In turn, this can lead to the creation of a supportive environment in which managers, identified as group leaders (Chrobot-Mason, Ruderman, Weber, & Ernst, 2009), value employees who are striving for a better equilibrium between work and family life (O’Driscol et al., 2003; Allen, 2001; Thompson, Beauvais, & Lyness, 1999), eventually resulting in mutually beneficial outcomes for managers and firms alike (Kossek & Friede, 2006). Second, while prior studies have mainly focused on the investigation of the direct relationship between policies and job satisfaction (Greenhaus, Ziegert, & Allen, 2012; Kossek, Pichler, Bodner, & Hammer, 2011), the current study extends this research by proposing and testing a process model that considers both mediation and moderation mechanisms behind the role of the availability of WFP in ultimately influencing work attitudes. Understanding the pattern of relationships linking the availability of WFP to work-family conflict and subsequently to work attitudes (i.e., work engagement and organizational commitment) holds implications for the development of organizational initiatives and intervention strategies based on the factors that drive these outcomes (Shockley
RETURN TO WORK AFTER MATERNITY LEAVE

& Singla, 2011). Specifically, we argue that WFP represent a job resource likely to influence work attitudes not only through a direct path but also as a buffering factor limiting the negative effects of work-family conflict. Our theoretical model is illustrated in Figure 1.

---

INSERT FIGURE 1 ABOUT HERE

---

Third, while previous meta-analyses reported mixed findings regarding the hypothesis that single policies were more strongly related to reduced work-family conflict than multiple ones (Butts et al., 2013), the need for investigating the role of different policy types on work-family conflict still requires empirical investigation (Sutton & Noe, 2005). Moreover, recent research posits that policies differ in the way they convey organizational control, with enabling policies giving employees latitude over when, where and how much they work, and enclosing policies that, on the other side, aim to maximize employees’ availability for work by providing services that remove employees’ need to leave work (Bourdeau, Ollier-Malaterre, & Houlfort, 20192018; Friedman, 2001). This study sets out to provide a first empirical investigation of the extent to which different bundles of policies relate to work-family conflict and different work attitudes. In doing so, this research contributes to advance theoretical and practical knowledge on the types of programs to be implemented in order to facilitate return to work after maternity leave.

THEORETICAL BACKGROUND

The relationship between work-family policies and work attitudes

Reflecting the changing workforce demographics, organizations have recently become more responsive to work-family issues, offering a more extensive array of formal WFP (Clark, Rudolph, Zhdanova, Michel, & Baltes, 2017). Work-family support policies represent one of the means through which organizations may respond to employee family needs (Swody &
RETURN TO WORK AFTER MATERNITY LEAVE

Powell, 2007), providing support to reduce conflicts and stress related to employees fulfilling multiple roles in life (Kossek, 2005). When role demands from one domain are incompatible with role demands in the other domain, this may result in adverse interactions between work and family (Greenhaus & Beutell, 1985).

Work-family conflict is highly probable to occur among employed parents who represent a group of people likely to feel the burden of multiple demands from work and non-work domains (Brough, O'Driscoll, & Biggs, 2009). Previous findings report that mothers are more vulnerable to role conflicts (Brough & O’Driscoll 2005; Brown, 2010; Freudenburg & Davidson, 2007; Losoncz & Bortolotto, 2009; Somech & Drach-Zahavy, 2007), which can be explained according to resource-drain theory postulating that personal resources are finite, and resources expended in one domain are not available in another (Edwards & Rothbard, 2000). That is, resource drain is likely to impact working mothers in the face of competing multiple-role demands, resulting in stress-related outcomes such as work-family conflict (Michel, Kotrba, Mitchelson, Clark, & Baltes, 2011). Women are likely to be hit especially hard by work-family conflict as these positions entail a significant amount of responsibility to the company’s financial performance, and female managers are more highly scrutinized than their male counterparts (Hoobler, Masterson, & Nkomo, 2018).

Building on the job demands-resources theory (JD-R; Bakker & Demerouti, 2007), we conceptualize WFP as a job resource. The JD-R assumes that all job characteristics within the work environment can be classified into job demands and job resources. Job demands are defined as “those physical, social, or organizational aspects of the job that require sustained physical or mental effort and are therefore associated with certain physiological and psychological costs” (Demerouti et al., p. 501). On the other side, job resources are conceptualized as “those physical, social, or organizational aspects of the job that either are...
RETURN TO WORK AFTER MATERNITY LEAVE

...functional in achieving work goals; reduce job demands and the associated physiological and psychological costs; or stimulate personal growth and development” (Demerouti et al., 2001, p.501). Whereas job demands are generally the most important predictors of negative work-related outcomes such as exhaustion (Bakker, Demerouti, & Schaufeli, 2003), job resources are generally the most important predictors of work motivation and engagement (Bakker et al., 2007).

Scholars argue that job resources are instrumental in achieving work goals and that they play an intrinsic motivational role because they satisfy the basic human need for either autonomy, relatedness, or competence (Schaufeli & Taris, 2014; Deci & Ryan, 2000). In this study, we argue that WFP can represent a means to achieve work goals, for example, when they are perceived as allowing better time-management or a means through which satisfying one’s basic need, e.g., the one for autonomy when they refer to flexible work arrangements. Accordingly, we place WFP as a specific job resource that, if coupled with others such as social support, development opportunities, and performance feedback, can serveable to stimulate positive work attitudes and reduce the negative impact of work-family conflict (Mauno, Kinnunen, & Ruokolainen, 2006). Research suggests that adopting the JD-R to the study of organizational policies can provide important insights to the design, implementation, and monitoring of such policies because it sheds light on the psychological processes underlying the development of work and organization outcomes associated with perceived resources and demands (Costantini, Sartori, & Ceschi, 2017). That is, in the context of this study, such a framework allows understanding whether and how specific WFP facilitate female managers’ coping with the job demands associated with motherhood, and if the availability of WFP can be particularly helpful at different levels of such perceived demands, eventually serving to support (or not) higher work-related well-being (Bakker et al., 2003).
RETURN TO WORK AFTER MATERNITY LEAVE

In line with such a conceptualization, previous findings showed that the availability of WFP exhibits small but favorable relationships with positive work attitudes (Butts et al., 2013), intentions to stay in the job (Thompson & Prottas, 2006), and a negative relationship with work-family conflict (Thompson et al., 1999). Accordingly, we propose the following:

Hypothesis 1: Policy availability negatively relates to work-family conflict.

Drawing on signaling theory (Spence, 1973), the availability of WFP may be interpreted as a symbol of corporate concern to employees’ family needs, likely to prompt positive work attitudes (Butts et al., 2013). That is, employees may interpret WFP as signals of corporate concern for their employees’ well-being, thereby forming impressions about a company’s motives (Goldberg & Allen, 2008). In turn, employees who feel supported by their organizations may feel obliged to reciprocate, which would translate into positive work and organization outcomes (Blau, 1964; Kossek & Thompson, 2016). Past findings support this argumentation, particularly with regards to the relationship between the availability of work-life benefits and increased organizational commitment (Allen, 2001; Behson, 2005; Casper & Harris, 2008; Grover & Crooker, 1995). Similarly, work engagement, which is substantially influenced by job resources (Schaufeli & Bakker, 2004), i.e., WFP, will be positively related to policy availability. Based on this, we propose the following:

Hypothesis 2: Policy availability positively relates to (a) affective commitment, (b) work engagement, (c) continuance commitment.

Work-family conflict and its relationship with work attitudes

Work-family conflict represents the most commonly studied experience at the work-family interface. Even if it has been defined as inherently non-directional (Greenhaus & Beutell, 1985), once a decision is made for resolving the conflict, it usually results in work-to-family interference (WFI) or family-to-work interference (Grzywacz & Smith, 2016). Several studies investigated how these different forms of conflict relate to organizational outcomes. Findings
RETURN TO WORK AFTER MATERNITY LEAVE

reported that WFI is positively related to continuance commitment (Casper et al., 2002; Lyness & Thompson, 1997) and that it predicts job dissatisfaction. Such a relationship has been argued to reflect the fact that employees who experience WFI, yet remain employed with their organizations, may attribute their commitment to aspects of “need” (i.e., they feel that they need to continue working in that environment; continuance commitment), as opposed to aspects related to “want” (i.e., the feeling of wanting to work in that environment). This may also suggest that mothers who experience WFI remain with their organizations out of necessity rather than choice (Casper et al., 2002). Research also reported evidence of a negative relationship between WFI and affective commitment, as well as with work engagement (Good, Sisler, & Gentry, 1988; Lyness & Thompson, 1997; Opie & Henn, 2013; Thompson et al., 1999).

Literature defines affective commitment as denoting an emotional attachment to the organization and continuance commitment as denoting the perceived costs associated with leaving it. Since WFI represents the type of conflict originating in the work domain, it may be associated with lower emotional attachment (i.e., affective commitment) to the organization (Casper et al., 2002). Moreover, drawing on findings supporting a source attribution perspective in linking WFI and attitudes (Shockley & Singla, 2011), it is likely that people would blame the organization for work interfering with family, eventually reporting lower intention to continue, i.e., lower continuance commitment.

Hypothesis 3: WFI negatively relates to (a) affective, and (b) continuance commitment.

Although an extensive body of literature investigated the relationship between WFI and several work outcomes, less attention has been paid to the study of the link between WFI and work engagement. Studies investigating the role of work engagement inside organizations showed its relevance for employees’ well-being and work behavior (Sonnentag, 2003) and that engaged employees transfer their engagement to others in their immediate environment (Bakker
RETURN TO WORK AFTER MATERNITY LEAVE

& Xanthopoulou, 2009). Even though work engagement does not represent a recurrent outcome associated with WFI, one notable exception is the study conducted by Opie and Henn (2013), who reported that WFI negatively predicts work engagement among mothers. Considering these findings, we propose that:

Hypothesis 3c: WFI negatively relates to work engagement.

A model of the psychological mechanisms between work-family policies, work-family conflict, and work attitudes

Building on the relationships described in the previous hypotheses, work-family conflict represents a mediator of the relationship between WFP and work attitudes. Accordingly:

Hypothesis 4: Work-family conflict mediates the relationship between the availability of WFP and work attitudes, i.e., organizational commitment and work engagement.

Moreover, drawing on the JD-R framework, we expect that the availability of different bundles of WFP will buffer the negative effects of WFI on affective commitment and work engagement. Indeed, previous findings reported that WFP relate to employee outcomes through lower work-life conflict (Beauregard & Henry, 2009). Along with previous hypotheses, this argument involves a moderated mediation process (MacKinnon, 2008; MacKinnon & Fairchild, 2009; Muller, Judd, & Yzerbyt, 2005) where:

Hypothesis 5: The availability of work-family policies buffers the negative relationship between WFI and work attitudes, such that the proposed mediation through work-family conflict is stronger when work-family policies are not available (Figure 1).

MATERIALS AND METHOD

Participants and procedure

Participation in the study was accomplished via a web-based survey mailed to 345 female managers from different companies operating throughout Italy in a variety of different segments. On average, it took 20 minutes to complete the questionnaire. Table 1 sums up the
RETURN TO WORK AFTER MATERNITY LEAVE

characteristics of the participants. Potential participants were recruited from a national web-community of female managers, from which we identified those stating in their profile of having at least one child under three years old. Of the total number of surveys mailed, 238 questionnaires were considered valid and usable for the study, for a response rate of 69%. All participants worked in a managerial position, were mothers, and reported a mode of 1 child. Thirty-seven percent of the participants stated they returned to work within the first six months from delivery, 47.6% within the first year, 10.6% within 18 months from delivery, and 4.2% within 24 months from delivery. The mean age of respondents was 34 years, ranging from 29 to 52.

INSERT TABLE 1 ABOUT HERE

Each participant was asked to complete questions on demographic and role-related variables (i.e., age, education, company’s sector), and a questionnaire measuring WFI, work-family enrichment, work engagement, and organizational commitment. All participants were given a notice containing a brief explanation of the purpose of the study and a statement ensuring the confidentiality of their results. Items were focused on the moment of organizational re-entry after childbirth by adding the following instruction before each scale: “Please note: These questions are about your overall situation since your return to work after maternity leave. Fill in the statements thinking about how you felt since you came back to work after your youngest child was born.” Question order was counterbalanced to avoid common method bias (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003).

Measures

WFI. Work interfering with family was assessed with six items of the short version of the work-family balance scale (Zhang et al., 2012). This scale has been developed based on the shortened version (13 items; Wooden, 2003) of Mashall and Barnett’s (1993) 26-item work-
RETURN TO WORK AFTER MATERNITY LEAVE

family strains and gains scale, which conceptualizes work-family balance as including work-family enrichment and work-family conflict (Grzywacz & Carlson, 2007). As for work-family conflict, the items capture aspects referring to work-family and work-parenting strains, i.e., multiple overloads and multiple-role conflict (Marshall & Barnett, 1993). A sample item is “Because of work, I often fail to take part in family activities”. Response options were on a 7-point rating scale from strongly disagree (1) to strongly agree (7). We also administered the six items measuring work-family enrichment (WFE) from the same scale. A sample item is “Work and family together enrich my life.” Results from a Pearson’s correlation indicated that the two scales were significantly and negatively correlated, $r = -.28; p < .01$, indicating that, in our sample, those experiencing high WFI also reported low enrichment.

**Work engagement.** Work engagement was assessed with 17-items from the Italian version of the Utrecht Work Engagement Scale (Pisanti, Paplomatas, & Bertini, 2008). This version includes six items for the vigor (e.g., “At my work, I feel bursting with energy”) and absorption (e.g., “I am immersed in my work”) dimensions, and five items for the dedication dimension (e.g., “I am enthusiastic about my job”). Items were scored on a 7-point rating scale ranging from 0 (never) to 6 (always). Based on results from Schaufeli, Bakker, and Salanova (2006), showing that the three dimensions are closely related, we used one overall index for work engagement (Cronbach’s $\alpha = .96$).

**Organizational commitment.** Seven items developed by Allen & Meyer (1991) assessed affective and continuance commitment. Three items measured the former (e.g., “This organization has a great deal of personal meaning for me”) and four the latter (e.g., “I feel that I have too few options to consider leaving this organization”). Responses were made on a 7-point rating scale from strongly disagree (1) to strongly agree (7). Cronbach’s $\alpha$ for the affective commitment scale was .77, and .79 for the continuance commitment scale.
RETURN TO WORK AFTER MATERNITY LEAVE

Availability of work-family support policies. We examined multiple policies that referred to different bundles, e.g., flexible time management, training projects on maternity leave and organizational re-entry, parenting and pregnancy policies, and organizational facilities. Participants were asked to indicate whether or not each policy was available in their organizations. Table 2 reports the items used to measure policy availability and the results of an exploratory factor analysis conducted to examine what policies were perceived as referring to the same bundle in participants’ perceptions. After that, policy availability was treated as a count variable, summing the policies available for each bundle extracted from the EFA. In particular, from the results of the EFA we extracted six factors (bundles) and summed the policies referred to each of such bundles: (a) Organizational facilities, which refer to policies aiming at providing employees services and spaces to help manage work and family; (b) Smart working, referring to policies aiming at allowing customization of the way in which working time/space is managed; (c) Parenting and pregnancy policies, which refer to the management of the maternity leave period; (d) Communication and psychological support, referring to the ways in which organizations provide specific measures to support information exchange and psychological support during pregnancy and/or maternity; (e) Flexible time management, referring to part-time arrangements and the management of lunch breaks; (f) Return to work management, which refers to measures allowing a mutual agreement of the return to work phase after maternity leave. Drawing on the assumption that policy availability must be observed by employees to be used (Thompson et al., 2004), policy availability was assessed as an individual-level measure of perceived availability rather than actual availability at the organizational level.
RETURN TO WORK AFTER MATERNITY LEAVE

Controls. We controlled for a number of demographic variables, including age, marital status, partner, and number of children. Our results did not change when including these; hence they were excluded from further analyses.

RESULTS

Table 3 shows the means, standard deviations, internal reliability values, and correlations among the variables of interest.

INSERT TABLE 3 ABOUT HERE

Before testing our hypotheses, we ran confirmatory factor analyses (CFAs) to explore the factorial structures of our measures using AMOS 21.0 with maximum likelihood estimation (Byrne, 2001). Since our policy measures are here conceptualized as formative constructs, i.e., explanatory combinations of indicators (Bollen & Bauldry, 2011; Fornell & Bookstein, 1982), we did not include them in the CFA. Accordingly, in order to check whether our policy measures were distinct from the other constructs, we checked the correlation matrix. Results (see Table 3) showed that the policy measures are correlated relatively low with the other constructs, indicating that they do not substantially overlap.

As for the CFA, we followed established recommendations to report our findings (Hu & Bentler, 1999; Schumacker & Lomax, 2004; Klein, Tosi, & Cannella, 1999). A model including the five study variables (WFI, WFE, affective commitment, continuance commitment, and work engagement) supported the discriminant validity of our measures: $\chi^2_{(536 df)} = 831.70, p < 0.001; \text{CFI} = .93; \text{TLI} = .92, \text{RMSEA} = .06, \text{SRMR} = .08.$

INSERT TABLE 4 ABOUT HERE
RETURN TO WORK AFTER MATERNITY LEAVE

Hypotheses 1 stated that policy availability should be negatively related to WFI. Results from regression analyses (see Table 5) revealed a significant negative beta coefficient for communication and psychological support ($\beta = -.26$, $p < .01$) and flexible time management ($\beta = -.31$, $p < .01$), providing partial support for Hypotheses 1. Hypotheses 2 predicted that the availability of WFP is positively related to affective and continuance commitment, as well as work engagement. Results from regression analyses revealed that the availability of organizational facilities ($\beta = .24$, $p < .01$), communication and psychological support ($\beta = .30$, $p < .01$), and flexible time management ($\beta = .33$, $p < .001$) positively predicted affective commitment, partially supporting Hypothesis 2a. The availability of organizational facilities ($\beta = .32$, $p < .001$), communication and psychological support ($\beta = .26$, $p < .01$), and flexible time management ($\beta = .32$, $p < .05$) was also found to be positively related to work engagement, partially confirming Hypothesis 2b. As for Hypothesis 2c, results showed that the availability of communication and psychological support ($\beta = -.29$, $p < .01$) and flexible time management ($\beta = -.27$, $p < .01$) negatively predicted continuance commitment. Hypotheses 3 stated that WFI is negatively related to organizational commitment and work engagement. Results from the regression analyses showed that continuance commitment was positively related to WFI ($\beta = .35$, $p < .001$), while work engagement and affective commitment were negatively related to WFI (respectively: $\beta = -.32$, $p < .001$; $\beta = -.30$, $p < .001$).

---------------------------

Hypothesis 4 investigated the mediating role of WFI in the relationship between the availability of WFP and work attitudes. In order to test such a Hypothesis, we used a bootstrap estimation approach with 5000 samples (Preacher & Hayes, 2008). Results are reported in Table 6 and show that, depending on the policy considered, WFI acts as a full mediator between policy availability and work attitudes. Findings showed that the availability of organizational facilities
RETURN TO WORK AFTER MATERNITY LEAVE

was no longer a significant predictor of affective commitment after controlling for WFI, \( B = .57, SE = .26, ns \), consistent with a full mediation. Likely, after controlling for WFI, flexible time management policies were no longer significantly associated with continuance commitment, \( B = -.33, SE = .18, ns \). The availability of parenting and pregnancy policies showed to be positively related to work engagement only when controlling for WFI, \( B = .66, SE = .28, 95\% CI = .09, 1.22 \), consistent with a partial mediation.

Finally, Hypothesis 5 stated that the availability of WFP moderates the mediation through WFI, is moderated by the availability of WFP. To test this Hypothesis, we utilized bootstrapping (Shrout & Bolger, 2002) as suggested by MacKinnon, Fairchild, and Fritz (2007). Results are reported in Table 6.

Results (see Table 7) revealed that among all the different policies considered, the availability of communication and psychological support policies and of flexible time management acted as variables influencing WFI and moderating the effects of conflict on work engagement. That is, the availability of communication and psychological support at the organization was significantly related to WFI (\( B = -.48, p < .001 \)), which in turn was significantly related to work engagement (\( B = -.32, p < .001 \)). Additionally, flexible time management was significantly related to WFI (\( B = -.57, p = .001 \)), which in turn was significantly related to work engagement (\( B = -.35, p < .001 \)). As expected, there was a significant indirect effect of both communication and psychological support and flexible time management on work engagement through WFI (respectively: \( B = .42, p < .05; 95\% CI [.08, .75] \); \( B = .50, p < .01; 95\% CI [.16, .84] \)), as well as a moderation effect of policy availability on the influence of WFI on work engagement (respectively, for communication and psychological support \( B = .35, p < .01< ; 95\% CI [.08, .62] \), for flexible time management \( B = \).
RETURN TO WORK AFTER MATERNITY LEAVE

.51, \( p = .001; \) 95%CI [.22, .79]). In both cases, the conditional indirect effect was significant for those reporting medium and low levels of WFP. The index of moderated mediation (Hayes, 2015) corresponded to -.17, 95%CI, [-.37, -.04] for communication and psychological support, and -.29, 95%CI, [-.58, -.09] for flexible time management.

DISCUSSION

This study focused on the psychological mechanisms through which the availability of WFP yields beneficial consequences for women in management positions who return to work after maternity leave. Following the basic premises of the JD-R theory (Bakker & Demerouti, 2014), in our study, we considered WFP as a job resource. Moreover, according to the buffering effect postulated in the JD-R theory, we expected WFP to moderate the negative effects of WFI on positive work attitudes, i.e., work engagement and organizational commitment. Our results contribute to the knowledge on how the availability of different bundles of WFP relates to managers’ work attitudes after they return to work following maternity leave, holding importance for both research and practice.

First, by adopting the JD-R theory to the study of boundary management (i.e., the ways in which individuals maintain, negotiate, and transition across work and family roles) from an organizational perspective (Allen, Cho, & Meier, 2014), our study contributes to the field of work-family boundary dynamics by answering the call to increase our understanding of the results and processes underlying the effectiveness of WFP. Moreover, by considering several types of policies, we were able to investigate how they differ in influencing WFI and work attitudes. Recent research suggests that, while WFP are often treated as if they were all created equal, they differ in the way organizational control is conveyed (Bourdeau et al., 2019). Accordingly, scholars argue that de-bundling policies permits to differentiate between enabling
RETURN TO WORK AFTER MATERNITY LEAVE

and enclosing mechanisms of control and to identify their effects on work attitudes. In our study, we show that different enclosing policies are linked to work attitudes while enabling ones are not. Consistently, our findings show that communication and psychological support, and flexible time management were either directly or indirectly related to work attitudes. Such policies represent enclosing ones, in that they encourage the management of maternity leave within rather than outside the organization. Indeed, even though flexible time management may suggest a more enabling mechanism of control, it refers to variations of the time around core business hours when employees must be at work, which is different from smart working policies that, on the contrary, refer to the ability to choose the work time of start/end, and/or the location from which to work (Bourdeau et al., 2019). Such findings may be explained based on the view that the status of motherhood may undermine the credibility of employees’ commitment (Correll, Benard, & Paik, 2007), with women in management positions who return to work valuing organizational support in the form of policies permitting to signal greater work devotion.

In the current study, the availability of communication and psychological support, as well as flexible time management, are both positively related to affective commitment and work engagement, and negatively related to continuance commitment. This may suggest that the availability of such policies is likely to sustain positive affective attitudes referred to the organization, which may counterbalance feelings of instrumental considerations related to continuance commitment. Our study also confirms that WFI is a negative predictor of work engagement. This is consistent with existing literature on the relationship between WFI and burnout (Ahmad, 2010) and WFI and work engagement (Opie & Henn, 2013). Moreover, partially in line with previous research, the current study provides evidence that WFI negatively influences affective commitment (Lyness & Thompson, 1997; Thompson et al., 1999), and positively influences continuance commitment (Casper et al., 2002). While experiencing WFI
RETURN TO WORK AFTER MATERNITY LEAVE

originating in the work domain is likely to affect emotional attachment to the organization negatively, it is also presumable that mothers who experience such negative situations, yet continue to work with their organization, may attribute such feelings to necessity, rather than choice, eventually reporting higher levels of continuance commitment.

When considering WFI as a mediator of the relationship between policy availability and work attitudes, organizational facilities show to be no longer significant positive predictors of affective commitment, while flexible time management policies were no longer negatively linked to continuance commitment. That is, for those reporting WFI, the effect of such a conflict undermines the importance of organizational facilities to feel emotionally attached to the organization, while also sustaining perceptions referred to the need for staying in an organization because of the perceived costs associated with leaving it. When considering WFI as a mediator between parenting and pregnancy policies and work engagement, the availability of such policies become a significant predictor of higher work engagement, suggesting that such policies are perceived as important when perceptions of WFI are involved.

The current study also provides evidence of a mediated moderation in which WFI partially mediates the relationship between the availability of communication and psychological support and flexible time management policies with work engagement, and policy availability moderates the relationship between WFI and work engagement. That is, for female managers working in organizations where such policies are available, the effects of WFI on work engagement are lowered. This may suggest that working mothers who experience WFI in organizations where these policies are available are more likely to experience a positive, fulfilling, work-related state of mind, which allows them to be absorbed into their work and focused less on the negative impact of the competing role demands between work and family domains. Flexible time management and communication and psychological support are useful not only to reduce conflict, either symbolically or actually (Kossek & Ozeki, 1998), but also to
RETURN TO WORK AFTER MATERNITY LEAVE

buffer the negative effects of conflict on work engagement. These findings support the assumptions of the JD-R theory, which hold that job resources are useful to attain work goals and to buffer the negative effects of perceived demands (i.e., WFI) on motivational states (Bakker & Demerouti, 2017). Moreover, results suggest possible avenues for enhancing the use of JD-R theory as a model to improve work-life initiatives by detailing the psychological mechanisms through which these might be effective in sustaining work-related well-being. Our findings show that female managers’ positive work perceptions after motherhood can be sustained via the provision of WFP because these can lower perceptions of work-family conflict and its effect on motivational states. This suggests that such policies may be perceived as particularly powerful symbols among our participants because they provide organizational mechanisms to manage the boundaries of the work-family interface. In turn, this is likely to lower perceptions of WFI, because the awareness that the organization provides chances to manage the increased responsibilities and maintain a good work reputation is likely to alleviate the pressure from the participation in multiple roles.

Finally, our study provides valuable insights about which policies can stimulate positive work attitudes that are likely to be transferred to others in the immediate environment, i.e., work engagement (Bakker & Xanthopoulou, 2009). Accordingly, offering policies that increase work engagement among managers may yield multiplicative benefits, which may spread to the entire organization. Previous evidence showed that when managers were viewed as being understanding and supportive of employees’ needs, individuals experienced not only less conflict between their work and family life but also greater commitment to their organization and higher levels of job satisfaction (O’Driscoll et al., 2003).

Overall, findings suggest that the JD-R approach can be used to advance the literature on work-life balance by shedding light on the indirect and interactive effects of certain WFP on different positive and negative outcomes. This is particularly relevant given that, to date, the
RETURN TO WORK AFTER MATERNITY LEAVE

The majority of studies on work interfering with family have focused only on direct relationships between work-family conflict and its outcomes (Rofcanin et al., 2017; Mauno et al., 2006). On the other side, such an approach also contributes to advance the JD-R theory by showing that “hybrid” crossover factors spanning different life domains. That is, policies and initiatives designed to support the daily management of responsibilities from spheres that are not limited to the work environment can have a significant role in sustaining motivational processes in the workplace.

Limitations and future research

Given the nature of the study, several limitations need to be considered when evaluating the results. First, the conclusions we draw from the present research are based on a relatively homogenous sample of Italian managers, which might affect the transcultural validity of our results. Also, even though our study offers some initial insights to understand the role of different enclosing and enabling policies on the development of work and organization outcomes, more research is needed to test whether the results would differ among other populations and controlling for policy use. Given that we collected measures on policy availability rather than use, our study suggests that employees’ awareness and interpretation of the signals sent through the availability of WFP can have an effect on both work engagement and commitment. Accordingly, organizations’ intentions to be supportive could also be signaled through different means that leverage, for example, on interpersonal communication and everyday acts (Grandey, Cordeiro, & Michael, 2007), which could be investigated in future studies.

Moreover, even though our results provide valuable insights into the role of WFP in fostering work engagement and affective commitment while lowering WFI among female managers with children, future research should try to replicate our study on participants including also males and participants without children, in order to compare results from different groups (e.g. single female managers without children or those who have taken
RETURN TO WORK AFTER MATERNITY LEAVE

(1) Although our participants were all mothers, we were not able to control for the effects of domestic and child-care help of participants’ role as primary caregivers. Research in this area may provide further insights to develop programs and policies targeted at the specific needs of organization members and accounting for their responsibilities in different life domains.

Although the cross-sectional data from our field study does not allow to draw definite causal conclusions (Butts et al., 2013) and reverse causality is possible (e.g., WFI influences the perception of WFP), our study was conceptualized under the premise that it is easier for companies to manipulate the presence of WFP and investigate the effects it has on WFI. Future studies should manipulate the presence of WFP experimentally to examine the causal direction in more detail. Moreover, future research could consider collecting data from both managers and employees in order to understand how managers’ experiences with WFP impact on their perceptions of employees using leave.

Finally, our study does not allow to draw conclusions about the extent to which our participants’ responses reflect the genuine choices of women in managerial roles returning to work after maternity leave rather than adherence to established norms regarding appropriate managerial roles. In this vein, it could be argued that WFP might indirectly serve to perpetuate stereotypical working patterns rather than to decrease women’s work-family conflict. Research in this area is needed to shed light on how WFP actually help in reducing work-family conflict, also depending on how WFP are experienced, interpreted, and used in possibly different ways. Along this line, future studies could also consider investigating whether the experienced quality of the provided policy has a role over work-related attitudes and work-family conflict.

CONCLUSIONS AND PRACTICAL IMPLICATIONS

The availability of communication and psychological support, as well as flexible time management, may result in higher affective commitment and work engagement for women in
RETURN TO WORK AFTER MATERNITY LEAVE

management positions who return to work after maternity leave. Moreover, this study shows
that the availability of flexible time management and communication and psychological support
lowers WFI and buffers its negative effect on work engagement.

These findings yield practical implications for developing HR policies aiming at
supporting the return to work after maternity leave. Although appointing women to leadership
roles within organizations can symbolize a modern approach to management (Eagly & Carli,
2003), we argue that organizational structures need to be in place in order to accommodate a
healthy work-life balance. Specifically, results indicate that organizations may support work-
related psychological well-being of women in management positions who recently become
mothers by (a) offering services and spaces to facilitate the efficient management of work and
family, (b) providing measures to support information exchange and psychological support
during pregnancy and maternity, and (c) offering part-time arrangements and flexible
management of breaks. Within current organizations, managers’ commitment to their
occupation leads to the proper delivery and implementation of organization practices and,
therefore, is deemed as a critical factor for the success of such practices (Oh, Blau, Han, & Kim,
2017). This may be especially interesting for countries with meager fertility rates and available
support such as Italy, where women who experienced maternity and hold high responsibilities
at work can contribute to reshaping discussions of women at work.
