Background: Long-acting (LA) injectable regimens are a potential therapeutic option in people living with HIV-1.

Setting: ATLAS (NCT02951052) and FLAIR (NCT02938520) were 2 randomized, open-label, multicenter, multinational phase 3 studies.

Received for publication May 1, 2020; accepted July 6, 2020.

Methods: Adult participants with virologic suppression (plasma HIV-1 RNA <50 copies/mL) were randomized (1:1) to continue with their current antiretroviral regimen (CAR) or switch to the long-acting (LA) regimen of cabotegravir (CAB) and rilpivirine (RPV). In the LA arm, participants initially received oral CAB + RPV once-daily for 4 weeks to assess individual safety and tolerability, before starting monthly injectable therapy. The primary endpoint of this combined analysis was antiviral efficacy at week 48 (FDA Snapshot algorithm: noninferiority margin of 4% for HIV-1 RNA \geq 50 copies/mL). Safety, tolerability, and confirmed virologic failure (2 consecutive plasma HIV-1 RNA \geq 200 copies/mL) were secondary endpoints.

Results: The pooled intention-to-treat exposed population included 591 participants in each arm [28% women (sex at birth), 19% aged \geq 50 years]. Noninferiority criteria at week 48 were met for the primary (HIV-1 RNA \geq 50 copies/mL) and key secondary (HIV-1 RNA <50 copies/mL) efficacy endpoints. Seven individuals in each arm (1.2%) developed confirmed virologic failure; 6/7 (LA) and 3/7 (CAR) had resistance-associated mutations. Most LA recipients (83%) experienced injection site reactions, which decreased in incidence over time. Injection site reactions led to the withdrawal of 6 (1%) participants. The serious adverse event rate was 4% in each arm.

Conclusion: This combined analysis demonstrates monthly injections of CAB + RPV LA were noninferior to daily oral CAR for maintaining HIV-1 suppression.

Key Words: long-acting, antiretroviral therapy, injectable, cabotegravir, rilpivirine, HIV

INTRODUCTION

HIV remains a major global health concern, with the Joint United Nations Programme on HIV/AIDS and the World Health Organization (WHO) estimating the number of people living with HIV (PLWH) to be ~37.9 million in 2018.^{1,2} Improvements in HIV treatment efficacy are reflected in the increases in longevity of PLWH.³ Despite this progress, the effectiveness of current antiretroviral therapy (ART) is challenged by the need to maintain high levels of adherence to sustain virologic suppression.⁴ Factors related to regimen complexity, such as dosing frequency and pill burden, food considerations, stigma, and drug–drug interactions between oral antiretrovirals and commonly prescribed non-ART medications, are reported to contribute to this challenge.^{4–6} Furthermore, the emotional burden of living with HIV may be compounded by daily oral pill taking and additional complexities.⁷ Therefore, there is considerable interest in developing long-acting (LA) treatments that can address many of these issues while simplifying ART for PLWH.⁸

The recommended ART regimen for PLWH generally consists of daily doses of either an oral 2-drug or 3-drug combination.^{9,10} This combination typically involves an integrase strand transfer inhibitor (INSTI) (dolutegravir as the sole INSTI preferred for use in adults in the WHO guidelines⁹ and either dolutegravir, bictegravir, or raltegravir preferred in the US Department of Health and Human

Services guidelines¹⁰), in combination with 2 nucleoside reverse transcriptase inhibitors (NRTIs); although, a single NRTI (lamivudine) in combination with dolutegravir has recently been recommended as a 2-drug regimen in HIV treatment guidelines.¹⁰

Cabotegravir (CAB) (GSK1265744) is an investigational INSTI and structural analog of dolutegravir.¹¹ Rilpivirine (RPV) is a next-generation non-NRTI (NNRTI) currently approved as a once-daily oral tablet to be used in combination with other antiretrovirals for the treatment of HIV infection.^{12,13} Both compounds are formulated as LA agents to be administered intramuscularly (IM), with oral formulations of RPV and a new formulation of CAB in development.¹³ These oral formulations have been used during an oral lead-in phase in the ATLAS¹⁴ and FLAIR¹⁵ studies to assess safety and tolerability before study participants transitioning to LA therapy with CAB and RPV. This 2-drug oral combination therapy of CAB and RPV was assessed in the LATTE (NCT01641809) study and shown to provide similar antiviral activity compared with efavirenz plus dual NRTIs.¹⁶

A single IM injection of CAB LA 800 mg or RPV LA 1200 mg demonstrated sustained mean or geometric mean plasma concentrations above their respective in vitro protein-adjusted 90% inhibitory concentrations (PA-IC₉₀) at 32 weeks postdose for CAB LA¹⁷ (PA-IC₉₀ 0.166 μ g/mL), and 24 weeks postdose for RPV LA¹⁸ (PA-IC₉₀ 12 ng/mL), providing rationale to investigate the 2 drugs as an LA combination regimen. In the LATTE-2 (NCT02120352) randomized, open-label phase 2b clinical trial, the injectable LA combination of CAB and RPV (CAB + RPV LA) as a 2-drug HIV-1 maintenance therapy, administered every 4 or 8 weeks, was similar to daily 3-drug oral therapy of CAB plus abacavir/lamivudine in maintaining viral suppression (plasma HIV-1 RNA <50 copies per/mL; FDA Snapshot algorithm) through 96 weeks.¹⁹ Together, these results supported phase 3 investigation of CAB + RPV LA.

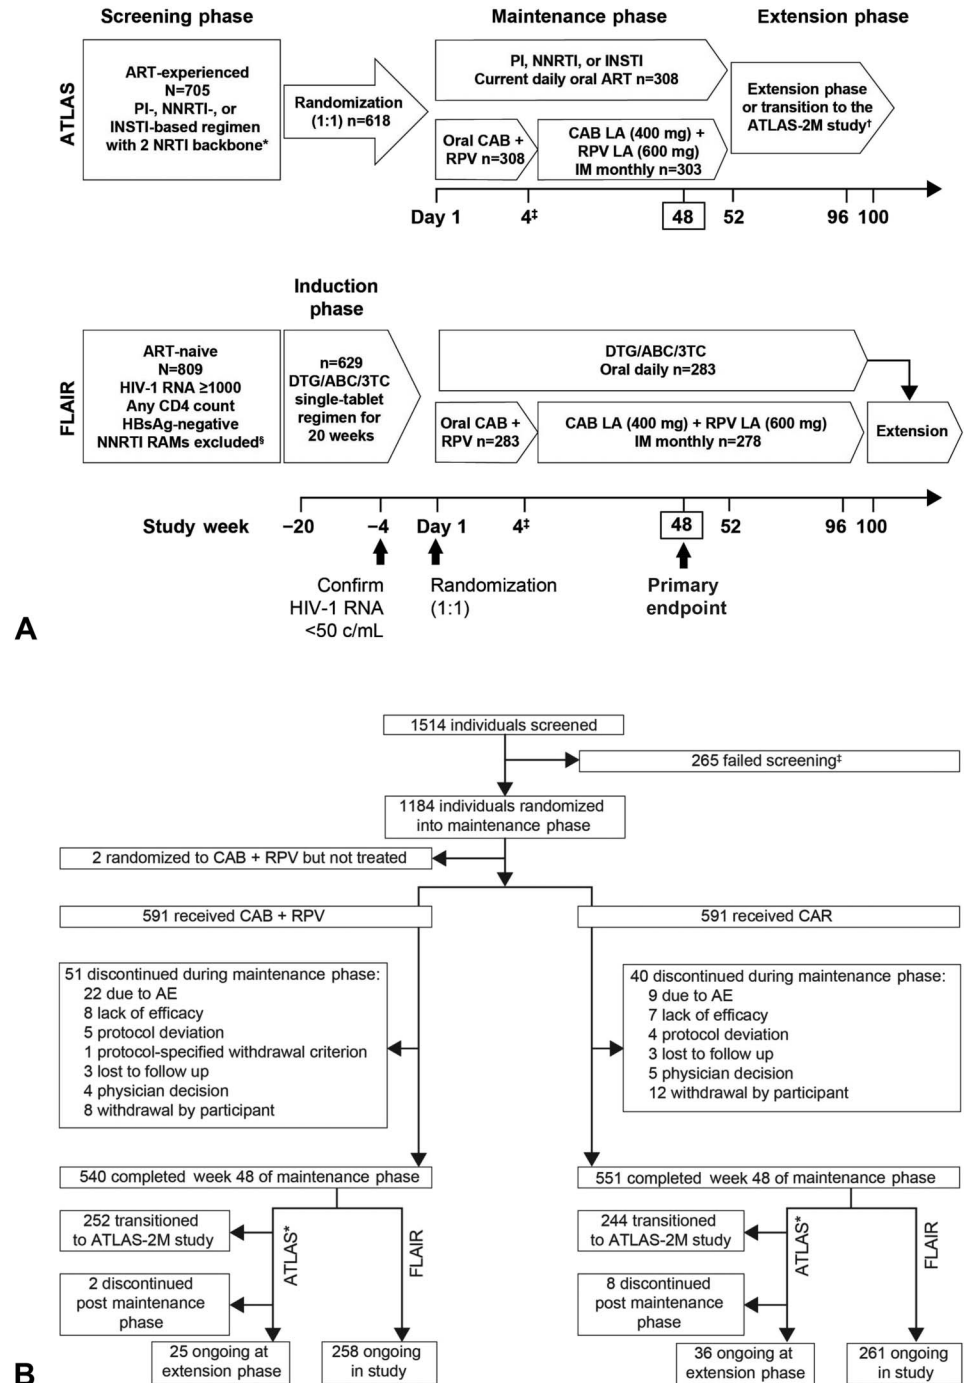

ATLAS (NCT02951052)¹⁴ and FLAIR (NCT02938520)¹⁵ are ongoing randomized, open-label, multinational phase 3 studies. These studies demonstrated that monthly injections of CAB + RPV LA were noninferior based on the primary endpoint (participants with plasma HIV-1 RNA \geq 50 copies/mL at week 48) compared with a control group who continued their oral current antiretroviral regimen (CAR). The individual results of these studies are published elsewhere.^{14,15} Here, we present the replanned pooled analyses of the efficacy (noninferiority), viral resistance, pharmacokinetic analysis, safety and tolerability, and preference findings observed in participants enrolled in the ATLAS and FLAIR studies.

METHODS

Study Design and Participants

ATLAS (NCT02951052) and FLAIR (NCT02938520) are randomized, multicenter, parallel-group, open-label phase 3 studies comparing CAB + RPV LA with CAR in ART-experienced PLWH-1 infection. Both studies comprised a screening phase, maintenance phase, and extension phase; participants in the FLAIR study initially received an induction

FIGURE 1. Study design and participant disposition. **A**, Study design. *Uninterrupted ART 6 months and VL <50 copies/mL at screening, 2 × VL <50 copies/mL ≤12 months (1 within the 6–12-month window, and 1 within 6 months prior to screening). †Optional switch to CAB + RPV LA at week 52 for those on CAR. ‡Participants received an initial loading dose of CAB LA (600 mg) and RPV LA (900 mg) at week 4. From week 8 onward, participants received CAB LA (400 mg) + RPV LA (600 mg) injections every 4 weeks. §The presence of any major INSTI or NNRTI resistance-associated mutation (except K103N) from prior genotype assay results were exclusionary. Figure adapted from Murray M, Antela A, Mills A, et al. Patient-Reported Outcomes in ATLAS and FLAIR Participants on Long-Acting Regimens of Cabotegravir and Rilpivirine Over 48 Weeks. *AIDS Behav.* 2020. <https://doi.org/10.1007/s10461-020-02929-8>, under a Creative Commons Attribution 4.0 International License, <http://creativecommons.org/licenses/by/4.0/>. 3TC, lamivudine; ABC, abacavir; CAB, cabotegravir; CAR, current antiretroviral therapy; DTC, dolutegravir; IM, intramuscular; HBsAg, hepatitis B surface antigen; PI, protease inhibitor; RAM, resistance-associated mutation; RPV, rilpivirine; VL, viral load. **B**, Participant disposition. *Participants who completed study participation at week 52 had the option to continue by entering the extension phase, transitioning to the ATLAS-2M study, or leaving the study (no withdrawal visit needed). The latter was not captured in this figure. ‡The remaining 65 participants in FLAIR were withdrawn from the study prior to randomization into the maintenance phase. CAR, current antiretroviral therapy; CAB, cabotegravir; RPV, rilpivirine.

antiretroviral regimen to achieve viral suppression before the maintenance phase (Fig. 1A). Details of the respective study designs are reported elsewhere.^{14,15}

Enrolled study participants were ≥18 years old, or ≥19 years where required by local regulations. In the FLAIR study, all participants received an initial fixed-dose oral regimen of 600 mg abacavir, 50 mg dolutegravir, and 300 mg lamivudine once-daily for 20 weeks before random-

ization (non-abacavir-based backbone was administered for participants positive for HLA-B*5701, and an alternative backbone was chosen for those intolerant to or who developed toxicity to any component of the backbone regimen). Participants with suppressed plasma HIV-1 RNA (<50 copies/mL) in both studies were randomized (1:1) to receive either CAB + RPV LA monthly IM injections or to continue their daily CAR. Randomization was stratified by: sex at birth and baseline HIV-

1 RNA (<100,000 or \geq 100,000 copies/mL) for FLAIR; sex at birth and baseline regimen third-agent class (protease inhibitor, INSTI, or NNRTI) for ATLAS. Participants in the LA arm received oral CAB + RPV until week 4 or longer (oral lead-in) before switching to the IM regimen. Oral therapy (bridging) with CAB + RPV was available for participants who were unable to make a scheduled visit within the injection window.

Participants with confirmed virologic failure (CVF; 2 consecutive plasma HIV-1 RNA measurements \geq 200 copies/mL) were discontinued from the study treatment. Participants who withdrew from LA therapy entered long-term follow-up (52 weeks). After completion of the maintenance phase of the study, participants had the option to continue/switch to the LA therapy for the duration of the extension phase, which is ongoing. ATLAS participants also had the option to rollover into the ongoing ATLAS-2M randomized study (NCT03299049), comparing CAB + RPV LA administered every 4 weeks vs every 8 weeks.²⁰

ATLAS and FLAIR were conducted in accordance with the Declaration of Helsinki.²¹ All participants provided written informed consent. The study protocol, any amendments, the informed consent, and other information that required pre-approval were reviewed and approved by a national, regional, or investigational center ethics committee or institutional review board.

Endpoints and Assessments of Pooled Analysis

The primary endpoint of this pooled analysis was the proportion of participants with plasma HIV-1 RNA levels \geq 50 copies/mL at week 48 by FDA Snapshot algorithm. The key secondary endpoint was the proportion of participants with plasma HIV-1 RNA <50 copies/mL at week 48. Selected secondary and exploratory endpoints included virologic outcomes by randomization strata and baseline subgroups, resistance analysis of participants with CVF through week 48, pharmacokinetic analysis, safety and tolerability, laboratory abnormalities, and participant preference.

Statistical Methods and Populations for Analysis

The planned participant number of 285 participants per arm in each study was chosen to appropriately power the statistical analyses of the primary and key secondary noninferiority endpoints of the individual studies. The overall sample size provided sufficient power to perform the pooled analysis. With the combined sample size of 570 participants per treatment arm, the study would have 90% power to demonstrate noninferiority for the primary endpoint of the proportion of participants with virologic failure at week 48 by the Snapshot intention-to-treat exposed (ITT-E) approach using a prespecified 4% noninferiority margin. The ITT-E population consisted of randomized participants who received at least 1 dose of study drug during the maintenance phase of the study (on or after day 1 visit). Participants were analyzed according to the randomized treatment arm. The safety population consisted of all randomized participants who

received at least 1 dose of study drug during the maintenance phase of the study (on or after day 1 visit).

The primary and key secondary efficacy analyses were based on the ITT-E population using the Snapshot algorithm. For the primary analysis, treatment with CAB + RPV LA was declared noninferior to CAR if the upper end limit of the 2-sided 95% confidence interval (CI) for the difference in proportions of participants with plasma HIV-1 RNA \geq 50 copies/mL between the 2 groups [(CAB + RPV LA)—CAR] at week 48 was less than 4%. For the key secondary efficacy analysis, treatment with CAB + RPV LA was declared noninferior to CAR if the lower limit of the 2-sided 95% CI for the difference in virologic suppression rates (HIV-1 viral load <50 copies/mL) between the 2 groups [(CAB + RPV LA)—CAR] at week 48 was greater than -10% (prespecified).

RESULTS

Participants

A total of 1514 individuals were screened (ATLAS, n = 705; FLAIR, n = 809) and 1184 were randomized (2 participants were randomized but did not receive treatment: 1 for non-compliance with study treatment, 1 for noncompliance with protocol procedures). Participant disposition is shown in Figure 1B. The baseline characteristics of participants in the LA and CAR arms were similar (Table 1 and see Figure S1, Supplemental Digital Content, <http://links.lww.com/QAI/B518>). Overall, 591 participants in each arm initiated the maintenance phase (n = 308 from ATLAS and n = 283 from FLAIR). Most participants were of white race (LA, 73%; CAR, 69%), with a median (range) age of 38 years (LA, 19–74 years; CAR, 18–82 years). Women accounted for >25% of participants (LA, 27%; CAR, 28%).

Efficacy

In the LA and CAR arms, 11 (2%) and 10 (2%) participants, respectively, had HIV-1 RNA \geq 50 copies/mL at week 48, with an adjusted treatment difference [LA—CAR (95% CI)] of 0.16% (-1.35 to 1.67), meeting the noninferiority criteria of the primary endpoint (4% noninferiority margin). The secondary endpoint was also met, with 550 (93%) LA participants and 558 (94%) CAR participants having HIV-1 RNA <50 copies/mL at week 48, with an adjusted treatment difference [LA—CAR (95% CI)] of -1.37% (-4.12 to 1.39), meeting the prespecified -10% noninferiority margin (Snapshot) (Table 2).

In the LA arm, 98% of the 6920 expected injection visits across the 2 studies occurred within the allowed \pm 7 days of the planned visit day. No participant who received an injection outside of the allowable dosing window met CVF criteria. In total, oral bridging ranging 4–61 days was utilized in 16 participants to cover missed (n = 7) or delayed (n = 9) injection visits.

Efficacy results were generally consistent between subgroups (see Figures S2 and S3, Supplemental Digital Content, <http://links.lww.com/QAI/B518>). However, a slightly higher proportion of women (sex at birth) and

TABLE 1. Pooled Participant Baseline Characteristics: ITT-E Population

	LA (n = 591)	CAR (n = 591)

*Two participants' data are missing.

†Collected at induction baseline (week –20) for FLAIR.

BMI, body mass index; CAR, current antiretroviral therapy; IQR, interquartile range; HCV, hepatitis C.

participants with a body mass index \geq 30 kg/m² in the LA arm had HIV-1 RNA \geq 50 copies/mL at week 48, with a difference in proportion (95% CI) of 2.49 (–0.64 to 6.54) and 3.06 (–2.54 to 9.72), respectively. Also, the LA arm was favored by the African American subgroup for the proportion of participants with HIV-1 RNA <50 copies/mL at week 48 [difference in proportion (95% CI) of 6.86 (0.12 to 13.90)].

Resistance Analysis

At week 48, 7 participants in each arm had CVF (2 consecutive plasma HIV-1 RNA measurements

\geq 200 copies/mL). This includes 1 participant in the LA arm of FLAIR who temporarily discontinued the oral lead-in dosing during a work-up for an apparent positive pregnancy test that was later confirmed to be a false positive result and, upon re-initiation, met the criteria for CVF; this participant, however, never received LA injections and was withdrawn from the study.

Of the 6 participants in the LA arm who received CAB + RPV LA, NNRTI (n = 6) and/or INSTI (n = 4) resistance mutations were present at the time of suspected virologic failure (Table 3). Four of these participants had HIV-1 subtype A1, 1 had subtype A, and 1 had subtype AG at baseline. Of the 6 participants, NNRTI (n = 2) resistance mutations and the INSTI L74I polymorphism (n = 5) were present at baseline; all retained full susceptibility to dolutegravir at suspected virologic failure timepoint (below clinical cut-off of 4.0-fold change). The participant who met CVF criteria during the oral lead-in phase had HIV-1 subtype AG with no resistance mutations detected.

Pharmacokinetics

Mean plasma CAB and RPV concentrations were well above their respective PA-IC₉₀ (CAB PA-IC₉₀, 0.166 μ g/mL; RPV PA-IC₉₀, 12 ng/mL)¹⁹ during the maintenance phase. At week 8, 4 weeks after the initial IM loading dose (initial trough concentration), pooled geometric mean (95% CI) plasma concentrations were 1.38 μ g/mL (1.31 to 1.46) for CAB and 39.88 ng/mL (38.05 to 41.80) for RPV, 8-fold and 3-fold above their respective PA-IC₉₀. At week 48, geometric mean (95% CI) plasma concentrations were 2.97 μ g/mL (2.85 to 3.10) for CAB and 86.42 ng/mL (82.87 to 90.14) for RPV, approximately 18-fold and 7-fold above their respective PA-IC₉₀ values and similar to those reported in the

TABLE 2. Pooled Efficacy Outcomes at Week 48: ITT-E Population

Outcome	LA, n = 591, n (%)	CAR‡, n = 591, n (%)	Difference, % (95% CI)§	Adjusted Difference, % (95% CI)

*In the CAR arm, there were 7 CVFs. In ATLAS, there were 4 CVFs in the CAR arm, 3 of whom had reverse transcriptase mutations (M184I; M184V + G190S; and M230M/I) detected in HIV-1 RNA samples from 1 participant each, and 1 had no mutations. In FLAIR, there were 3 CVFs in the CAR arm, all without treatment-emergent resistance mutations or phenotypic changes.

†Baseline genotype sequences were derived from peripheral blood mononuclear cell HIV-1 DNA in ATLAS and plasma HIV-1 RNA in FLAIR.

‡L74I was present in 5 out of 6 participants at baseline and at SVF timepoint. It is not considered an INSTI RAM by IAS–USA guidelines and has no impact on CAB activity.²⁸

§Monogram biological cut-offs: RPV = 2.0, CAB = 2.5; Monogram clinical cut-off: DTG = 4.0.

||FLAIR had 1 participant who had oral CAB + RPV dosing interrupted because of a false-positive pregnancy test and, upon re-initiation of oral therapy, had SVF that was confirmed.

¶INSTI genotype and INSTI phenotype could not be generated at SVF timepoint (week 28). Therefore, week 24 plasma was sent for virology analyses, shown here. CAB, cabotegravir; CAR, current antiretroviral therapy; DTG, dolutegravir; RAM, resistance-associated mutation; RPV, rilpivirine; SVF, suspected virologic failure.

LATTE-2 study.¹⁹ Individual plasma CAB and RPV concentrations in participants with CVF at the time of failure were below the population means but, for most participants, were within the overall range of exposures for individuals who maintained virologic suppression. CAB/RPV plasma concentrations of those with CVF are presented in the individual ATLAS and FLAIR supplementary sections.^{14,15}

Safety and Tolerability

Adverse events (AEs) through week 48 are presented in Table 4. When excluding injection site reactions (ISRs), AEs were reported by 86% (n = 506) and 75% (n = 444) of participants in the LA and CAR arms, respectively. Most of these were grade 1 or 2, with 7% (n = 44) and 6% (n = 35) of participants in the LA and CAR arms, respectively, reporting an AE of grade ≥3. Drug-related AEs (excluding ISRs) occurred in 28% (n = 165) of participants in the LA arm compared with 6% (n = 35) in the CAR arm. AEs leading to withdrawal were reported for 22 (4%) participants in the LA arm and 9 (2%) participants in the CAR arm (specific reasons for withdrawal are listed in Table 4). Serious AEs were similar in both arms. Two serious AE occurrences were considered by investigators to be related to the study treatment: right knee mono-arthritis in the LA arm and suicidal ideation in the CAR arm. One death occurred during the maintenance phase due to a methamphetamine overdose

(CAR arm). This was determined to be unrelated to study treatment. AEs during the oral lead-in period occurred in 32% (n = 187) of participants; the 3 most commonly occurring were headache [3% (n = 17)], nasopharyngitis, and vitamin D deficiency [both 3% (n = 16)]. Mean (SD) weight change at week 48 from baseline was an increase of 2.34 kg (5.67) and 1.17 kg (5.22) in the LA and CAR arms, respectively.

Seventeen (3%) participants in the LA arm and 6 (1%) participants in the CAR arm had alanine aminotransferase elevations ≥3 times the upper limit of normal. Eleven (2%) and 3 (<1%) participants in the LA and CAR arms, respectively, met protocol-defined liver-related stopping criteria. Of these, 7 were diagnosed with hepatitis A, 3 with hepatitis B, 2 with hepatitis C, and 1 with hepatitis E; none were considered to represent drug-induced liver injury. Other laboratory evaluations were unremarkable.

Throughout the course of the maintenance phase, 14,682 injections were given to 581 participants. A total of 3663 ISRs were reported, accounting for 25% of all injections administered across the study period, <1% (n = 34) of which were grade ≥3 (see Table S1, Supplemental Digital Content, <http://links.lww.com/QAI/B518>). No grade 4 or 5 ISRs were reported. Most ISRs (88%) resolved within 7 days (median 3 days). Injection site pain was the most common event, reported with 21% (n = 3087) of injections, 1% of which (n = 32) were grade 3. Nodule, induration, and swelling were

TABLE 4. Pooled Adverse Events Through Week 48

Event category, n (%)	LA (n = 591)	CAR (n = 591)
Any AE	561 (95%)	444 (75%)
Excluding ISRs	506 (86%)	444 (75%)
Any grade ≥ 3 AE*	63 (11%)	35 (6%)
Excluding ISRs	44 (7%)	35 (6%)
Any AEs leading to withdrawal†	22 (4%)	9 (2%)
Any SAE	24 (4%)	25 (4%)
SAEs related to study treatment (excluding ISRs)‡	1 (<1%)	1 (<1%)
Any drug-related AE	490 (83%)	35 (6%)
Excluding ISRs	165 (28%)	35 (6%)
Any grade ≥ 3 drug-related AE*	28 (5%)	1 (<1%)
Excluding ISRs	8 (1%)	1 (<1%)
Any injection site pain§	458 (79%)	N/A
Grade ≥ 3 severity§	21 (4%)	N/A
Leading to withdrawal§	6 (1%)	N/A
Common AEs ($\geq 5\%$ in either arm) excluding ISRs		
Nasopharyngitis	108 (18%)	88 (15%)
Headache	71 (12%)	38 (6%)
Upper respiratory tract infection	66 (11%)	52 (9%)
Diarrhea	52 (9%)	38 (6%)
Pyrexia	43 (7%)	13 (2%)
Back pain	40 (7%)	23 (4%)
Influenza	41 (7%)	34 (6%)
Vitamin D deficiency	31 (5%)	24 (4%)
Nausea	30 (5%)	16 (3%)
AEs of special interest		
Anxiety	27 (5%)	20 (3%)
Depression	16 (3%)	14 (2%)
Suicidal ideation/behavior	4 (<1%)	5 (<1%)

*There was only 1 (<1%) participant with a grade 5 AE (death) in the CAR arm during the maintenance phase, which was due to a methamphetamine overdose that was determined to be unrelated to study treatment.

†AEs leading to withdrawal in >1 participant in the LA arm were injection site pain (n = 6); hepatitis (hepatitis A, n = 4; acute hepatitis B and C, n = 3 and n = 1, respectively); headache (n = 2); and diarrhea (n = 2). No single AE leading to withdrawal was reported in >1 participant in the CAR arm.

‡Serious AEs related to study treatment: LA arm, right knee mono-arthritis; CAR arm, suicidal ideation.

§Percentages based on number of participants who received at least 1 injection (n = 581).

CAR, current antiretroviral therapy; SAE, serious AE.

other reported ISRs, occurring in 140 (<1%), 136 (<1%), and 86 (<1%) of administered injections. Six (1%) participants discontinued treatment because of ISRs, comprising injection site pain in all cases (Table 4) either alone or with injection site nodule (n = 1) and/or injection site swelling (n = 1). The incidence of ISRs was highest at week 4, with ISRs experienced by 70% of participants. The incidence decreased over the course of the 48 weeks, occurring in 16% of participants at Week 48 (see Figure S4, Supplemental Digital Content, <http://links.lww.com/QAI/B518>).

Rates of AEs in the LA arm were similar between men and women (sex at birth), with any AEs and drug-related AEs reported in 91% (n = 148) and 78% (n = 126) of women, respectively, compared with 96% (n = 413) and

85% (n = 365) in men, respectively. Of those who received at least 1 injection, ISRs were reported in 81% (n = 128/159) of women and 86% (n = 361/422) of men. Discontinuation because of ISRs was 1% (n = 2) in women and <1% (n = 4) in men.

Preference

At weeks 24 and 44, there was a significant increase from baseline in treatment satisfaction of injectable therapy in participants in the LA arm compared with the CAR arm (see Figure S5, Supplemental Digital Content, <http://links.lww.com/QAI/B518>). Of the participants who responded to the preference survey, 98% (523/532) preferred the LA regimen.

DISCUSSION

The pooled results of the ATLAS and FLAIR studies described here demonstrate that monthly IM injections of CAB + RPV LA are noninferior to CAR in maintaining HIV-1 virologic suppression in treatment-experienced participants. The results of the primary and secondary endpoints were generally similar between subgroups. The findings are consistent with the individual results of the ATLAS and FLAIR studies,^{14,15} with this analysis gaining increased power because of the pooling of the data. The high proportion of participants with virologic success (HIV-1 RNA <50 copies/mL) with LA therapy at week 48 (93%) in this analysis is similar to previous phase 3 noninferiority switch studies such as SWORD-1 and -2.²²

The number of participants with CVF in the LA arm was low, occurring in 7 (1%) participants through week 48. This proportion is comparable to other large switch studies, which also reported incidences of $\leq 1\%$.^{22,23} Excluding the 1 participant who discontinued oral lead-in dosing because of a false-positive pregnancy test, all of these participants had NNRTI (n = 6) and/or INSTI (n = 4) resistance-associated mutations at time of suspected virologic failure. All except 1 (ATLAS, subtype AG) of these participants were subtype A1 or A. All but the ATLAS participant with subtype AG had the polymorphism L74I. However, subsequent in vitro investigations of viruses from those participants with CVF in the FLAIR study compared the observed INSTI resistance-associated mutations with or without the L74I polymorphism, and concluded that subtype A1 or B did not differ with respect to sensitivity to CAB.²⁴ Despite the presence of INSTI resistance-associated mutations, all participants retained full susceptibility to dolutegravir and 5/6 were subsequently resuppressed on alternative ART (HIV-1 RNA <50 copies/mL).

Because of the small sample size of participants with CVF, no definitive conclusions can be made on factors that could have contributed to CVF. No single factor alone (eg, sex at birth, body mass index, region, race, age, or prior NNRTI use) seemed to drive Snapshot or CVF (Table 2; see Figure S2, Supplemental Digital Content, <http://links.lww.com/QAI/B518>; data on file). The roles of certain patient and viral factors, such as pharmacokinetics, HIV-1 subtype, and

L74I polymorphism, are being evaluated to further define their contributions toward virologic failure development.

Overall, excluding ISRs, the observed AE profile with CAB + RPV LA therapy was similar to that in the CAR arm and is in line with the previously reported safety profile of CAB + RPV oral therapy.¹⁶ Despite ISRs being common (25% of administered injections), most were mild (99% grade 1 or 2). Overall incidence of ISRs steadily decreased throughout the study (week 4, 70%; week 48, 16%) and the duration of ISRs was short (median 3 days). These data suggest the initial high incidence of ISRs may have been because of initiation of a novel treatment administration route (IM injection), with a reduced incidence over the longer term as participants became more familiar with the injection procedure.

Both studies enrolled a substantial number of women (sex at birth) [ITT-E populations: ATLAS, 33% (n = 203); FLAIR, 22% (n = 127)], exceeding that targeted for inclusion in the individual studies (25% in ATLAS, 20% in FLAIR). This is an important achievement given that women are often under-represented in ART clinical trials,²⁵ despite accounting for the majority of adults living with HIV globally (WHO estimates, 2018).^{1,2} In this analysis, efficacy was comparable between men and women.

In the era of highly active ART, developing therapies that cause minimal disruption to the daily lives of PLWH is a key goal of current research efforts. Along with reducing exposure to the number of ART agents compared with traditional 3-drug regimens, CAB + RPV LA reduces the dosing frequency from daily to monthly. Some populations of PLWH may therefore find this a preferable option to their daily CAR, potentially facilitating improved adherence in those who report factors such as pill burden and forgetfulness as barriers to adherence.⁴ The Positive Perspectives study involving over 1000 PLWH found that most regarded daily ART as a “reminder of their HIV status,” whereas 25% felt “being tied to daily medication limited their day to day life.”⁷ Monthly CAB + RPV LA injections may therefore represent a more discreet regimen that could help some PLWH avoid the stigma associated with their HIV status. CAB + RPV LA would also enable the first option for directly observed therapy because of the monthly clinic visits required. This would result in more frequent interactions with health care professionals, which could potentially improve retention in care. Therefore, CAB + RPV LA may be a welcome treatment option for such populations of PLWH who are virally suppressed and see monthly injections as a beneficial trade-off for freedom from daily ART; however, the impact of monthly visits on HIV clinics will need to be considered.

Further to CAB + RPV LA being a welcomed treatment option compared with daily ART, nearly all of the participants who completed the preference question preferred the LA regimen over the oral regimen (98%). This is consistent with findings from the LATTE-2 study, in which participants also reported a preference for CAB + RPV LA therapy compared with daily oral ART.²⁶

Although the reduced dosing frequency of CAB + RPV LA may be beneficial to some PLWH, this needs to be specifically assessed in different populations, particularly those with adherence challenges. LATITUDE (NCT03635788), a

study investigating CAB + RPV LA in PLWH with a history of suboptimal adherence, will provide further clarity in this regard.²⁷ In addition, the present analysis is limited by the relatively short duration of treatment (48 weeks). Longer-term data will be provided by the 96-week results. In addition, there was likely a selection bias with the ATLAS and FLAIR studies, whereby only PLWH who were interested in an LA IM injectable regimen were likely to enroll. However, CAB + RPV LA is intended to add a novel therapy option to the treatment armamentarium for those willing to receive injections who may benefit from reduced dosing frequency.

In summary, the once-monthly regimen of CAB + RPV LA was noninferior to CAR in maintaining HIV-1 suppression in individuals with a prior treatment history of 20 weeks to many years of suppressive ART. These efficacy and safety results indicate CAB + RPV LA can be a potential therapeutic approach for virologically suppressed PLWH-1.

ACKNOWLEDGMENTS

The authors thank everyone who has contributed to the success of the studies: all study participants and their families, and the ATLAS and FLAIR clinical investigators and their staff. ATLAS and FLAIR are funded by ViiV Healthcare and Janssen. Professional medical writing and editorial assistance was provided by Daniel Williams, MSc, at SciMentum (Nucleus Global), and funded by ViiV Healthcare.
