15
16 A simple and rapid ultra-high performance liquid chromatography-mass
17 spectrometry/mass spectrometry (UPLC-MS/MS) method has been developed for
18 measuring intracellular concentrations of the anticancer agent 7-ethyl-10-
19 hydroxycamptothecin (SN-38) in tumour cells using camptothecin (CPT) as internal
20 standard. SN-38 extraction was carried out using acidified acetonitrile. SN-38 and CPT
21 were separated on a PFP column using gradient elution with acidified water and
22 acetonitrile. SN-38 and CPT were quantified using a triple quadrupole mass spectrometry
23 system. Least square regression calibration lines were obtained with average correlation
24 coefficients of $R^2 = 0.9993 \pm 0.0016$. The lower limit of detection (LOD) and lower limit
25 of quantification (LOQ) for SN-38 were 0.1 and 0.3 ng/ml, respectively. CPT recovery
26 was $98.5 \pm 13\%$ and SN-38 recoveries at low quality control (LQC, 5ng/ml) and high
27 quality control (HQC, 500ng/ml) were $89 \pm 6\%$ and $95 \pm 8\%$, respectively. The intra- and
28 inter-day imprecision for LQC was 6.0 and 9.2%, and for HQC was 4.7 and 7.1%.,
29 respectively. The method was compared to a validated high performance liquid
30 chromatography-fluorescent method. In addition, the method has been successfully
31 applied to determine the intracellular accumulation of SN-38 investigating the transport
32 through ABCB1 (P-gp) and ABCG2 (BCRP) efflux pumps in colorectal cancer cell lines.

method comparison.

1. Introduction

Irinotecan is mainly used in the treatment of colorectal cancer either alone or in combination with other drugs. SN-38 is the active metabolite of irinotecan (**Figure 1**). Irinotecan is converted to 7-ethyl-10-hydroxycamptothecin (SN-38) by human carboxylesterase (hCE) [1]. Irinotecan belongs to a class of anti-cancer drugs known as topoisomerase I poisons. Topoisomerase I enzymes allow DNA to relax by causing single stranded breaks, unwinding of DNA for replication to occur, and then re-annealing of the DNA double helix. If single stranded breaks remain due to the binding of SN-38, it ultimately leads to apoptosis of the affected cell.

SN-38 can undergo glucuronic acid conjugation and thus detoxification to form SN-38 glucuronide inside the body. The extent to which this occurs can greatly alter the side effects of irinotecan therapy such as diarrhoea [2]. Polymorphisms of UDP-glucuronosyltransferase (UGT) 1A1 enzyme can be associated with accumulation of SN-38 with increased risk of toxicity [3]. Therefore, plasma concentrations of SN-38 could serve as a useful marker predicting toxicity when irinotecan is given to cancer patients. In addition, intracellular concentrations of SN-38 are also thought to vary due to efflux of SN-38 via drug efflux pumps such as breast cancer-related protein (ABCG2). This efflux system may vary between tumour types and confers resistance to the drug [4]. So, measuring intracellular SN-38 could serve as an additional marker for drug activity/toxicity in patients.

1
2
3
4 Previous HPLC quantitative methods described for SN-38 were mainly for plasma or
5 liposomes as opposed to intracellular measurements [5-14]. Some of the plasma methods
6
7 were adapted to quantify intracellular SN-38 but without full validation of the optimised
8
9 methods [15,16]. Other groups [17,18] have successfully developed specific methods for
10
11 intracellular measurements. However, these methods were aimed primarily at separating
12
13 the lactone and hydroxy forms of SN-38 and involved complex chromatography leading
14
15 to long run times. In addition, SN-38 peak tailing was notable despite the use of ion
16
17 pairing. Therefore, we have developed and validated this novel ultra-high performance
18
19 liquid chromatography-mass spectrometry/mass spectrometry (UPLC-MS/MS) method
20
21 specifically for the determination of intracellular total SN-38 (hydroxy + lactone); with the
22
23 aims of shortening the run time and improving SN-38 peak resolution. The method was
24
25 developed using a pentafluoryl phenyl (PFP) UPLC column which allowed fast analysis
26
27 and good peak shape without the need for ion-pairing agents. Moreover, the method
28
29 applicability was tested in a panel of colorectal cancer cell lines and the results were
30
31 compared to a validated high performance liquid chromatography-fluorescent (HPLC-
32
33 Flu) method which have been used in a number of previous studies [4,19,20].

23 **2.2 Instrumentation, chromatographic and mass spectrometry conditions**

24
25
26
27
28 SN-38 and CPT were separated on an Accela UPLC system, Thermo Scientific, (Hemel
29
30 Hempstead, UK) equipped with Kinetex 1.7 μm PFP, LC Column 100 × 2.1 mm obtained
31
32 from Phenomenex, (Macclesfield, Cheshire, UK). Gradient elution was employed using a
33
34 mobile phase of 0.1% FA in water (buffer A) and 0.1% FA in ACN (buffer B) as follows:
35
36 Buffer A = 70% at 0 min, from 70 to 10% over 2 minutes, held at 10% for 1 minute, from
37
38 10 to 70% over 0.1 minutes, ending with 70% for 3 minutes, all at a flow rate of 250
39
40 μl/min.
41
42
43
44

45 Triple-stage-quadrupole mass spectrometry (TSQ) Vantage system, Thermo Scientific,
46
47 (Hemel Hempstead, UK) equipped with an electrospray ion source was used for mass
48
49 detection. Samples were analyzed in the Multiple Reaction Monitoring (MRM), positive
50
51 mode at a spray voltage of 3500 V. Nitrogen was used as sheath and auxiliary gases at a
52
53 flow rate of 30 and 10 arbitrary units, respectively. Argon was used as collision gas with
54
55 pressure of 1.5 mTorr. The optimum transitional daughter ion mass and collision energy
56

58
59
60
61
62
63
64
65

1
2
3
4 for SN-38 was: m/z 393.1 → 349.4 (collision energy 25V) and for CPT: m/z 349.1 →
5
6
7 305.4 (collision energy 23V). Data acquisition and chromatography analysis were carried
8
9
10 out using Xcalibur software version 2.2 from Thermo Scientific, UK.

11
12
13
14 The HPLC-Flu system consisted of Perkin Elmer series 200 HPLC system (Perkin Elmer,
15
16
17 Cambridge, UK) equipped with Luna ODS, C18(2), 3 μm, 150 × 4.6mm ID, from
18
19
20 Phenomenex (Macclesfield, Cheshire, UK), fitted with a C18 security guard cartridge
21
22
23 also from Phenomenex (Macclesfield, Cheshire, UK). Analytes were eluted using an
24
25
26 isocratic mobile phase consisting of 50 mM NaH₂PO₄ buffer (pH 3.1) containing 10 mM
27
28
29 SDS 65%: ACN 35%. At a flow rate of 1 ml/min. Analytes were detected using Perkin
30
31
32 Elmer series 200 HPLC fluorescence detector equipped with a xenon lamp operating at
33
34
35 wavelengths of 380 and 540 nm for excitation and emission, respectively. Data
36
37
38 acquisition and chromatography analysis was carried out using Turbochrom software
39
40
41 version 6.2.1 from Perkin Elmer (Cambridge, UK).

42 **2.3 Cell extraction procedure**

43
44
45
46 Cell samples were pelleted by centrifugation at 600 g, each containing 6 million cells.
47
48
49 After removal of supernatant, 200μl of 50% ACN containing 0.5% FA and 1 μg/ml CPT
50
51
52 was added to each sample, vortexed for 60 seconds and placed on ice for 30 min to allow
53
54
55 protein precipitation to occur. Samples were then spun at 10,000 g, 4 °C, for 10 min to
56
57
58 pellet the cell precipitate. 150μl supernatant was then transferred into LC-MS vials and
59
60
61 10 μl injected directly into the UPLC-MS system.
62
63
64
65

1
2
3
4
5
6
7 **2.4 Preparation of standards and controls**
8
9

10
11 SN-38 and CPT stock solutions were prepared at 1 mg/ml by dissolving in DMSO and
12 chloroform/methanol (4:1 vol:vol), respectively.
13
14

15
16
17
18 Working standards of SN-38 at the following concentrations 0.1, 0.3, 1, 3, 10, 30, 100,
19 300 and 1000 ng/ml were prepared by diluting SN-38 stock in pooled drug free cell
20 pellets. Quality control samples (QC) of 5, 50 and 500 ng/ml were prepared by dilution of
21 SN-38 stock in pooled drug free cell pellets.
22
23
24
25
26
27

28
29
30
31 Linearity of the assay was determined by injecting the working standards into the UPLC
32 system. The peak area of each analyte concentration was divided by the peak area of CPT
33 internal standard. The resultant ratio was then plotted against the concentration using a
34 weighted ($1/x^2$) quadratic least square regression model, where x is the concentration and
35 y is the peak area ratio.
36
37
38
39
40
41
42
43
44

45 **2.5 Sensitivity**
46
47

48
49
50 The lower limited of detection (LOD) was determined as the concentration of extracted
51 SN-38 that had a peak area ratio 3 times higher than the baseline noise. The lower limit of
52 quantitation (LOQ) was determined as the lowest conc. of extracted SN-38 with
53 imprecision < 10% and inaccuracy <15%.

2.6 Imprecision and inaccuracy

Interday imprecision was determined by extraction and analysis of three QC samples of known concentration 5 ng/ml (Low Quality Control; LQC), 50 (Middle Quality Control; MQC) and 500 ng/ml (High Quality Control; HQC) over 6 different days.

Intraday imprecision was determined by extraction and analysis of 6 replicates of each of the two QC samples within the same run.

Inaccuracy was determined by calculating the percentage deviation of the measured concentration from the nominal values of each QC sample.

2.7 Extraction recovery

Extraction efficiency (%) was determined at two QC levels (LQC and HQC) by dividing the peak areas from extracted samples with those from spiked post-extracted blank cell extract samples at the same QC concentration. Recovery of the CPT was determined in the same way at a concentration of 1 µg/ml.

2.8 Specificity for SN-38 and CPT

1
2
3
4 Specificity was evaluated by injecting blank mobile phase to conform that no peaks were
5
6 co-eluting at the positions of SN-38, CPT. This was also repeated with drug free (blank)
7
8 cell extract.
9

10 11 12 13 14 **2.9 Stability**

15
16
17
18
19 Stability of SN-38 and CPT were evaluated by repeated injection of standards after freeze
20
21 thaw cycles over a 3 month period of time.
22
23

24 25 26 **2.10 Application of method**

27
28
29
30
31 This method was used to determine intracellular SN-38 concentrations in human cancer
32
33 cell lines derived from colon cancer (HT29, HCT116 and SW620) in the presence and
34
35 absence of fumitremorgin C (a known ABCG2 efflux inhibitor) and Ciclosporin A (P-gp
36
37 efflux inhibitor).
38
39

40
41
42
43 Cells were grown in appropriate media in 90 ml flasks, trypsinized and counted prior to
44
45 the experiment. Samples of each cell line were then distributed to Falcon tubes at a
46
47 concentration of 2 million cells /ml (3 ml in each falcon tube). Each sample was then
48
49 treated with 0.1 μ M SN-38, with and without 10 μ M ciclosporin or 5 μ M Fumitremorgin
50
51 C. Incubated at 37°C for 2hrs to allow uptake/efflux to occur, after which, samples were
52
53 spun at 600 g, 4°C, for 6min to pellet cells. After removal of supernatant the cells were
54
55 washed once in ice cold hanks and transferred into 1.7ml Eppendorf tubes. Samples were
56
57
58
59
60
61
62
63
64
65

1
2
3
4 then re-spun at 600 g, 4°C, for 6 min to pellet cells. Cell extraction procedure was then
5
6 carried out as previously described in section 2.3.
7
8
9

10 11 **3. Results**

12 13 14 15 16 17 **3.1 Method development and optimisation**

18
19 Two different UPLC columns (PFP and HILIC) were investigated. SN-38 and CPT could
20
21 not be chromatographically separated on the HILIC column (Kinetex HILIC, 2.1 ×
22
23 100mm) using 80% acetonitrile isocratic elution at a flow rate of 250µl. SN-38 peak full
24
25 width at half maximum height (FWHM) was 0.1 minutes and retention time was 1.15
26
27 minutes (data not shown). These results suggested that SN-38 was not retained enough on
28
29 the HILIC column as the void time on this system was expected to be 0.96 minutes.
30
31 However, the PFP column produced efficient retention and sharp peaks using a simple
32
33 mobile phase gradient of water and ACN (Figure 2). Finally, the gradient was optimized
34
35 to achieve high throughput analysis.
36
37
38
39
40
41
42
43

44 **3.2 Extraction recovery**

45
46 Extraction recoveries were reproducible and consistent across 6 independent experiments
47
48 (total of 203 samples) with mean values of $98.5 \pm 13\%$ for CPT. SN-38 recoveries at
49
50 LQC and HQC (total of 24 samples) was $89 \pm 6\%$ and $95 \pm 8\%$, respectively.
51
52
53
54
55

56 **3.3 Standard curves and linearity**

57
58
59
60
61
62
63
64
65

1
2
3
4 The mean response factor across 6 experiments (standards were run in duplicate) was
5
6
7 239.5 ± 18.2 (Stdev). The average r^2 was 0.9993 ± 0.0016 . (**Table 1**). The imprecision at
8
9 the 0.1 ng/ml concentration was not acceptable (34.1%), so this calibrator point was
10
11 removed from the standard curve used in quantifying intracellular SN-38.
12
13

14 15 16 **3.4 Imprecision and Inaccuracy** 17

18
19 Intra-day imprecision was less than 6.0% over 6 experiments. Highest imprecision was
20
21 noted with LQC. The mean measured value for the LQC was 5.1 ± 0.3 with inaccuracy of
22
23 1.2%. The mean measured concentration for HQC was 492.0 with inaccuracy of -1.6%
24
25 (**Table 2**).
26
27

28
29
30
31 Inter-day imprecision were less than 9.2% across 6 experiments. The mean measured
32
33 value for the LQC was 5.1 ± 0.5 with inaccuracy of 1.9%. The mean measured
34
35 concentration for HQC was 491.5 with inaccuracy of -1.7% (**Table 2**).
36
37

38 39 40 41 **3.5 Sensitivity** 42

43
44 As shown in **Figure 2 (E) and Table 1**, although SN-38 was detectable at a
45
46 concentration of 0.1ng/ml, the imprecision at this concentration exceeded 10%. Therefore
47
48 LOQ was identified as 0.3 ng/ml and LOD identified as 0.1 ng/ml. The impression at
49
50 LOQ and LOD was 8 and 34%, respectively.
51
52

53 54 55 **3.6 Specificity** 56 57 58 59 60 61 62

1
2
3
4 Extracted blank cell extract showed no peaks eluting at the retention times of SN-38 and
5
6 CPT (1.75 and 1.89 minutes, respectively). **Figure 3 (D & G)** shows example
7
8 chromatograms for blank cell extracts with no co-eluting compounds at the expected
9
10 retention time of SN-38 and CPT, respectively.
11
12
13
14

15 16 **3.7 Freeze-thaw stability** 17 18 19 20

21 The results of the stability experiments are shown in **Table 3**. SN-38 stock solution was
22
23 found to be stable at -40°C for 3 months with a concentration difference of less than 5%
24
25 after 3 months of storage. The analytical method is therefore proved to be applicable for
26
27 routine analysis over this period of time.
28
29
30
31
32

33 34 **3.8 Method Application** 35

36 **Figure 3** shows that Cyclosporin A had little effect on the accumulation of SN-38 in the
37
38 three colorectal cell lines with significant increase of 57% in HT29 cell line ($p < 0.05$).
39
40 These results suggest that ABCB1 has a minor role in SN-38 efflux. However,
41
42 Fumitremorgin C (a specific ABCG2 inhibitor) resulted in a dramatic increase in SN-38
43
44 intracellular concentrations in all colorectal cell lines with 4.3, 2.1 and 3.1 fold increase
45
46 in HT29, HCT116 and SW620 cell lines, respectively. Combined administration of
47
48 cyclosporin A and fumitremorgin C did not result in more SN-38 accumulation compared
49
50 to fumitremorgin C alone treatment. These results suggest that SN-38 efflux in colorectal
51
52 cell lines is mainly via ABCG2.
53
54

56
57
58
59
60
61
62
63
64
65

3.9 UPLC-MS/MS Vs HPLC-Flu Method Comparison

This novel UPLC-MS/MS method resulted in sharp peak shapes for both SN-38 and CPT. FWHM for SN-38 and CPT was >0.1 minute for UPLC-MS method compared to 0.2 and 0.3 minutes, respectively for the HPLC-Flu method. The retention times obtained for the UPLC-MS method were 1.75 and 1.89 minutes for SN-38 and CPT, respectively compared to 3.7 and 4.6 minutes for the HPLC-Flu. This resulted in a shorter total run time for the UPLC-MS method (6 minutes compared to 7 minutes for HPLC-Flu). In addition, the UPLC-MS method had higher sensitivity with LOQ value of 0.3 ng/ml compared to 1 ng/ml for HPLC-Flu. The fluorescent detection of the HPLC-Flu method was saturated at a SN-38 concentration of 300 ng/ml, while the mass spectrometry detector of the UPLC-MS method detected SN-38 concentrations up to 10,000 ng/ml without saturation. Therefore, this novel UPLC-MS method covered a wider dynamic range (0.3-1000ng/ml compared to 1-200 ng/ml for HPLC-Flu). Imprecision and inaccuracy values were < 10% for both methods. The two methods were used to determine intracellular SN-38 concentrations in a panel of colorectal cancer cell lines. The results were then compared using Bland-Altman analysis in order to determine the degree of agreement between the two methods (**Figure 3D**). The average bias between the two methods was close to zero (0.16 ng/ml). In addition, the 95% limits of agreement were between +8.29 and -7.97 ng/ml.

4. Conclusion

The method described in this work is the first UPLC-MS method to be developed specifically for intracellular quantification of SN-38. The extraction method is simple and reproducible with high extraction yield. The method is highly sensitive, precise and accurate. A good separation was achieved with excellent peak resolution and minimal peak tailing without using any ion pairing agents. Moreover, the chromatography run time was shorter permitting high sample throughput. This method has been successfully applied to the measurement of intracellular SN-38 accumulation in a number of colorectal cell lines studying SN-38 efflux. In all the studied cell lines, SN-38 efflux was found to be mainly regulated by ABCG2 with minimal contribution of ABCB1. These results suggest that the newly developed UPLC-MS method is ideally suited for this type of analysis.

- An UPLC-MS/MS method was developed for measuring intracellular concentrations SN-38
- SN-38 was separated using a pentafluorophenyl UPLC column
- Fast analysis and good peak shape obtained without the need for ion-pairing agents.
- Method was used to investigate SN-38 efflux in colorectal cancer cell lines.
- The method results were compared to a validated HPLC- fluorescent method.
